What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

2 Electrical Characteristics

This section contains electrical specification tables and reference timing diagrams for the microcontroller unit, including detailed information on power considerations, DC/AC electrical characteristics, and AC timing specifications.

NOTE

The parameters specified in this data sheet supersede any values found in the module specifications.

2.1 Maximum Ratings

Table 4. Absolute Maximum Ratings[1, 2]

Rating	Symbol	Value	Unit
Supply voltage	V_{DD}	–0.3 to +4.0	V
Clock synthesizer supply voltage	V_{DDPLL}	–0.3 to +4.0	V
RAM standby supply voltage	V_{STBY}	+1.8 to 3.5	V
USB standby supply voltage	V_{DDUSB}	–0.3 to +4.0	V
Digital input voltage [3]	V_{IN}	–0.3 to +4.0	V
EXTAL pin voltage	V_{EXTAL}	0 to 3.3	V
XTAL pin voltage	V_{XTAL}	0 to 3.3	V
Instantaneous maximum current Single pin limit (applies to all pins)[4, 5]	I_{DD}	25	mA
Operating temperature range (packaged)	T_A (T_L - T_H)	–40 to 85 or 0 to 70[6]	°C
Storage temperature range	T_{stg}	–65 to 150	°C

1 Functional operating conditions are given in DC Electrical Specifications. Absolute Maximum Ratings are stress ratings only, and functional operation at the maxima is not guaranteed. Stress beyond those listed may affect device reliability or cause permanent damage to the device.

2 This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (V_{SS} or V_{DD}).

3 Input must be current limited to the I_{DD} value specified. To determine the value of the required current-limiting resistor, calculate resistance values for positive and negative clamp voltages, then use the larger of the two values.

4 All functional non-supply pins are internally clamped to V_{SS} and V_{DD}.

5 The power supply must maintain regulation within operating V_{DD} range during instantaneous and operating maximum current conditions. If positive injection current ($V_{in} > V_{DD}$) is greater than I_{DD}, the injection current may flow out of V_{DD} and could result in the external power supply going out of regulation. Ensure that the external V_{DD} load shunts current greater than maximum injection current. This is the greatest risk when the MCU is not consuming power (e.g., no clock).

6 Depending on the packaging; see orderable part number summary (Table 2)

Table 7. Current Consumption in Low-Power Mode, Code From SRAM[1,2,3]

Mode	8 MHz (Typ)	16 MHz (Typ)	64 MHz (Typ)	80 MHz (Typ)	Unit	Symbol
Stop mode 3 (Stop 11)[4]	0.090				mA	I_{DD}
Stop mode 2 (Stop 10)[4]	7					
Stop mode 1 (Stop 01)[4,5]	9	10	15	17		
Stop mode 0 (Stop 00)[5]	9	10	15	17		
Wait / Doze	13	18	42	50		
Run	16	21	55	65		

1 All values are measured with a 3.3 V power supply. Tests performed at room temperature.
2 Refer to the Power Management chapter in the *MCF52259 Reference Manual* for more information on low-power modes.
3 CLKOUT, PST/DDATA signals, and all peripheral clocks except UART0 off before entering low-power mode. CLKOUT is disabled. Code executed from SRAM with flash memory shut off by writing 0x0 to the FLASHBAR register.
4 See the description of the Low-Power Control Register (LPCR) in the *MCF52259 Reference Manual* for more information on stop modes 0–3.
5 Results are identical to STOP 00 for typical values because they only differ by CLKOUT power consumption. CLKOUT is already disabled in this instance prior to entering low-power mode.

5 Loss of Reference Frequency is the reference frequency detected internally, which transitions the PLL into self clocked mode.
6 Self clocked mode frequency is the frequency at which the PLL operates when the reference frequency falls below f_{LOR} with default MFD/RFD settings.

10 Jitter is the average deviation from the programmed frequency measured over the specified interval at maximum f_{sys}. Measurements are made with the device powered by filtered supplies and clocked by a stable external clock signal. Noise injected into the PLL circuitry via V_{DDPLL} and V_{SSPLL} and variation in crystal oscillator frequency increase the C_{jitter} percentage for a given interval.

2.9 USB Operation

Table 15. USB Operation Specifications

Characteristic	Symbol	Value	Unit

2.10 Mini-FlexBus External Interface Specifications

A multi-function external bus interface called Mini-FlexBus is provided with basic functionality to interface to slave-only devices up to a maximum bus frequency of 80 MHz. It can be directly connected to asynchronous or synchronous devices such as external boot ROMs, flash memories, gate-array logic, or other simple target (slave) devices with little or no additional circuitry. For asynchronous devices a simple chip-select based interface can be used.

All processor bus timings are synchronous; that is, input setup/hold and output delay are given in respect to the rising edge of a reference clock, MB_CLK. The MB_CLK frequency is half the internal system bus frequency.

The following timing numbers indicate when data is latched or driven onto the external bus, relative to the Mini-FlexBus output clock (MB_CLK). All other timing relationships can be derived from these values.

2.12 General Purpose I/O Timing

GPIO can be configured for certain pins of the QSPI, DDR Control, timer, UART, Interrupt and USB interfaces. When in GPIO mode, the timing specification for these pins is given in Table 21 and Figure 11.

The GPIO timing is met under the following load test conditions:

- 50 pF / 50 Ω for high drive

- 25 pF / 25 Ω for low drive

Table 21. GPIO Timing

NUM	Characteristic	Symbol	Min	Max	Unit
G1	CLKOUT High to GPIO Output Valid	t_{CHPOV}	—	10	ns
G2	CLKOUT High to GPIO Output Invalid	t_{CHPOI}	1.5	—	ns
G3	GPIO Input Valid to CLKOUT High	t_{PVCH}	9	—	ns
G4	CLKOUT High to GPIO Input Invalid	t_{CHPI}	1.5	—	ns

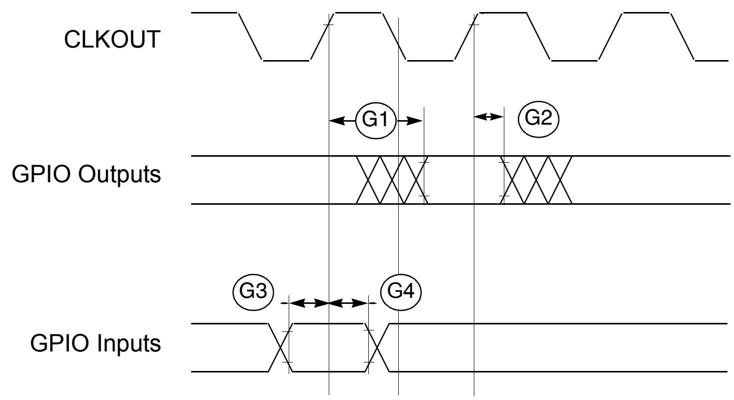

Figure 11. GPIO Timing

2.13 Reset Timing

Table 22. Reset and Configuration Override Timing

(V_{DD} = 3.0 to 3.6 V, V_{SS} = 0 V, $T_A = T_L$ to T_H)[1]

NUM	Characteristic	Symbol	Min	Max	Unit
R1	$\overline{RSTI}$ input valid to CLKOUT High	t_{RVCH}	9	—	ns
R2	CLKOUT High to $\overline{RSTI}$ Input invalid	t_{CHRI}	1.5	—	ns
R3	$\overline{RSTI}$ input valid time [2]	t_{RIVT}	5	—	t_{CYC}
R4	CLKOUT High to $\overline{RSTO}$ Valid	t_{CHROV}	—	10	ns

[1] All AC timing is shown with respect to 50% V_{DD} levels unless otherwise noted.

[2] During low power STOP, the synchronizers for the $\overline{RSTI}$ input are bypassed and $\overline{RSTI}$ is asserted asynchronously to the system. Thus, $\overline{RSTI}$ must be held a minimum of 100 ns.

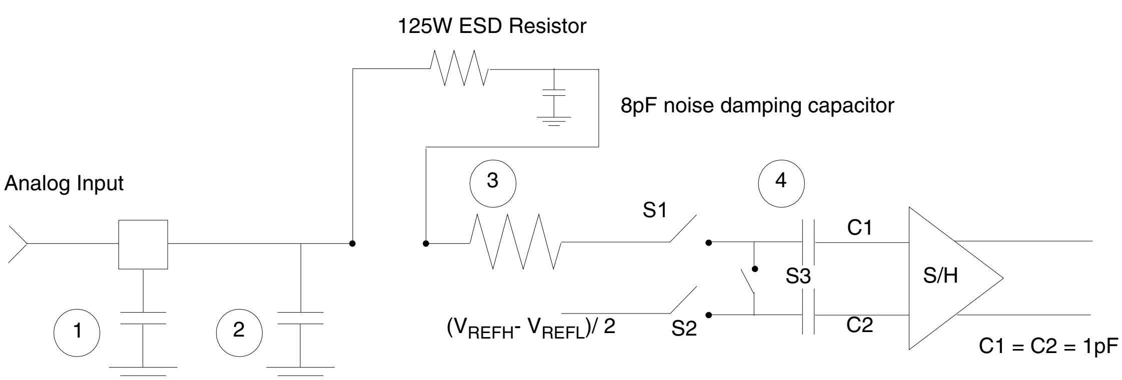
5 Includes power-up of ADC and V_{REF}
6 ADC clock cycles
7 Current that can be injected or sourced from an unselected ADC signal input without impacting the performance of the ADC

2.16 Equivalent Circuit for ADC Inputs

Figure 14 shows the ADC input circuit during sample and hold. S1 and S2 are always open/closed at the same time that S3 is closed/open. When S1/S2 are closed and S3 is open, one input of the sample and hold circuit moves to $(V_{REFH}-V_{REFL})/2$, while the other charges to the analog input voltage. When the switches are flipped, the charge on C1 and C2 are averaged via S3, with the result that a single-ended analog input is switched to a differential voltage centered about $(V_{REFH}-V_{REFL})/2$. The switches switch on every cycle of the ADC clock (open one-half ADC clock, closed one-half ADC clock). There are additional capacitances associated with the analog input pad, routing, etc., but these do not filter into the S/H output voltage, as S1 provides isolation during the charge-sharing phase. One aspect of this circuit is that there is an on-going input current, which is a function of the analog input voltage, V_{REF} and the ADC clock frequency.



1. Parasitic capacitance due to package, pin-to-pin and pin-to-package base coupling; 1.8 pF
2. Parasitic capacitance due to the chip bond pad, ESD protection devices and signal routing; 2.04 pF
3. Equivalent resistance for the channel select mux; 100 Ω
4. Sampling capacitor at the sample and hold circuit. Capacitor C1 is normally disconnected from the input and is only connected to it at sampling time; 1.4 pF
5. Equivalent input impedance, when the input is selected = $\frac{1}{(\text{ADC Clock Rate}) \times (1.4\times10^{-12})}$
