Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Table 3: **eFUSE Programming Conditions(1)**

Symbol	Description	Min	Typ	Max	Units
V_{FS}(2)	External voltage supply	3.2	3.3	3.4	V
I_{FS}	V_{FS} supply current	–	–	40	mA
V_{CCAUX}	Auxiliary supply voltage relative to GND	3.2	3.3	3.45	V
R_{FUSE}(3)	External resistor from R_{FUSE} pin to GND	1129	1140	1151	Ω
V_{CCINT}	Internal supply voltage relative to GND	1.14	1.2	1.26	V
t_j	Temperature range	15	–	85	°C

Notes:

1. These specifications apply during programming of the eFUSE AES key. Programming is only supported through JTAG.The AES key is only supported in the following devices: LX75, LX75T, LX100, LX100T, LX150, and LX150T.
2. When programming eFUSE, V_{FS} must be less than or equal to V_{CCAUX}. When not programming or when eFUSE is not used, Xilinx recommends connecting V_{FS} to GND. However, V_{FS} can be between GND and 3.45 V.
3. An R_{FUSE} resistor is required when programming the eFUSE AES key. When not programming or when eFUSE is not used, Xilinx recommends connecting the R_{FUSE} pin to V_{CCAUX} or GND. However, R_{FUSE} can be unconnected.

Notes:

1. The C_{IN} measurement represents the die capacitance at the pad, not including the package.
2. Maximum value specified for worst case process at 25°C. LX75, LX75T, LX100, LX100T, LX150, and LX150T only.
3. Refer to IBIS models for R_{DT} variation and for values at V_{CCAUX} = 2.5V. IBIS values for R_{DT} are valid for all temperature ranges.
4. V_{CCO2} is not required for data retention. The minimum V_{CCO2} for power-on reset and configuration is 1.65V.
5. Termination resistance to a V_{CCO}/2 level.

Notes:

1. V_{CCO} range required when using I/O standard for an output. Also required for MOBILE_DDR, PCI33_3, LVCMOS18_JEDEC, LVCMOS15_JEDEC, and LVCMOS12_JEDEC inputs, and for LVCMOS25 inputs when V_{CCAUX} = 3.3V.
2. For PCI systems, the transmitter and receiver should have common supplies for V_{CCO}.

Notes:

1. Using PLL_RXDIVSEL_OUT = 1, 2, and 4.
2. All jitter values are based on a Bit Error Ratio of $1e^{-12}$.
3. Using 80 MHz sinusoidal jitter only in the absence of deterministic and random jitter.
4. Composed of 0.37 UI DJ in the form of ISI and 0.18 UI RJ.
5. Measured using PRBS7 data pattern.

Endpoint Block for PCI Express Designs Switching Characteristics

The Endpoint block for PCI Express is available in the Spartan-6 LXT devices. Consult the Spartan-6 FPGA Integrated Endpoint Block for PCI Express for further information.

Output Delay Measurements

Output delays are measured using a Tektronix P6245 TDS500/600 probe (< 1 pF) across approximately 4" of FR4 microstrip trace. Standard termination was used for all testing. The propagation delay of the 4" trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in Figure 4 and Figure 5.

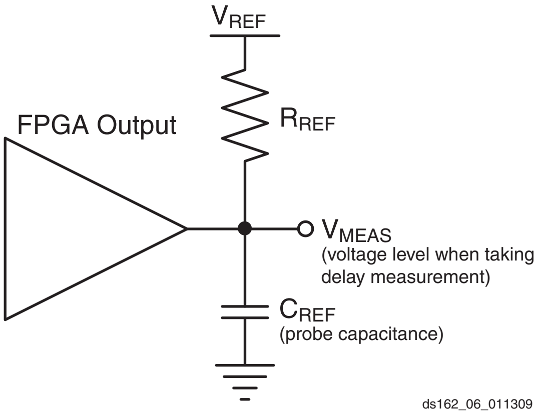

Figure 4: **Single-Ended Test Setup**

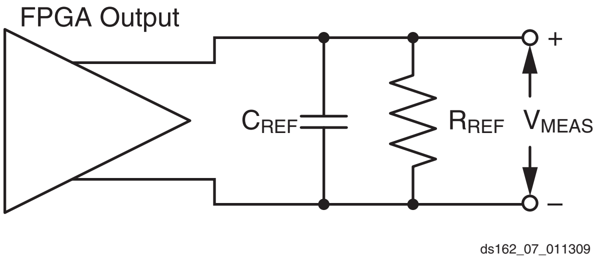

Figure 5: **Differential Test Setup**

Measurements and test conditions are reflected in the IBIS models except where the IBIS format precludes it. Parameters V_{REF}, R_{REF}, C_{REF}, and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using the following method:

1. Simulate the output driver of choice into the generalized test setup, using values from Table 32.
2. Record the time to V_{MEAS}.
3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS}.
5. Compare the results of steps 2 and 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

Simultaneously Switching Outputs

Due to package electrical parasitics, a given package supports a limited number of simultaneous switching outputs (SSOs) when using fast, high-drive outputs. Table 33 and Table 34 provide guidelines for the recommended maximum allowable number of SSOs. These guidelines describe the maximum number of user I/O pins of an output signal standard that should simultaneously switch in the same direction, while maintaining a safe level of switching noise for that particular signal standard. Meeting these guidelines for the stated test conditions ensures that the FPGA operates free from the adverse effects of GND and power bounce.

For each device/package combination, Table 33 provides the number of equivalent V_{CCO}/GND pairs per bank. For each output signal standard and drive strength, Table 34 recommends the maximum number of SSOs, switching in the same direction, allowed per V_{CCO}/GND pair within an I/O bank. The guidelines are categorized by package style, slew rate, and output drive current. The number of SSOs are also specified by I/O bank. Multiply the appropriate numbers from each table to calculate the maximum number of SSOs allowed within an I/O bank. The guidelines assume that all pins within a bank use the same I/O standard. Exceeding these SSO guidelines can result in increased power or GND bounce, degraded signal integrity, or increased system jitter. For a given I/O standard, if the SSO limit per pair in Table 34 is greater than the maximum I/O per pair in Table 33, then there is no SSO limit for the exclusive use of that I/O standard.

The recommended maximum SSO values assume that the FPGA is soldered on a printed circuit board and that the board uses sound design practices. Due to the additional inductance introduced by the socket, the SSO values do not apply for FPGAs mounted in sockets. The SSO values assume that the V_{CCAUX} is powered at 3.3V. Setting V_{CCAUX} to 2.5V provides better SSO characteristics. For more detail, see UG381: *Spartan-6 FPGA SelectIO Resources User Guide.*

Notes:

1. SSO limits greater than the number of I/O per V_{CCO}/GND pair (Table 33) indicate No Limit for the given I/O standard. They are provided in this table to calculate limits when using multiple I/O standards in a bank.
2. Not available (N/A) indicates that the I/O standard is not available in the given bank.
3. When used with the MCB, these signals are exempt from SSO analysis due to the known activity of the MCB switching patterns. SSO performance is validated for all MCB instances. MCB outputs can, in some cases, exceed the SSO limits.

Notes:

1. LXT devices are not available with a -1L speed grade.
2. Values for this parameter are available in the Clocking Wizard.
3. The PLL does not filter typical spread spectrum input clocks because they are usually far below the bandwidth filter frequencies.
4. Includes global clock buffer.
5. Calculated as F_{VCO}/128 assuming output duty cycle is 50%.
6. When using CLK_FEEDBACK = CLKOUT0 with BUFIO2 feedback, the feedback frequency will be higher than the phase frequency detector frequency. $F_{PFDMAX} = F_{CLKFB}$ / CLKFBOUT_MULT

Symbol	Description	Amount of Phase Shift	Units
Phase Shifting Range			
MAX_STEPS(2)	When CLKIN < 60 MHz, the maximum allowed number of DCM_DELAY_STEP steps for a given CLKIN clock period, where T = CLKIN clock period in ns. When using CLKIN_DIVIDE_BY_2 = TRUE, double the clock-effective clock period.	±(INTEGER(10 x (TCLKIN – 3 ns)))	steps
	When CLKIN ≥ 60 MHz, the maximum allowed number of DCM_DELAY_STEP steps for a given CLKIN clock period, where T = CLKIN clock period in ns. When using CLKIN_DIVIDE_BY_2 = TRUE, double the clock-effective clock period.	±(INTEGER(15 x (TCLKIN – 3 ns)))	steps
FINE_SHIFT_RANGE_MIN	Minimum guaranteed delay for variable phase shifting.	±(MAX_STEPS x DCM_DELAY_STEP_MIN)	ps
FINE_SHIFT_RANGE_MAX	Maximum guaranteed delay for variable phase shifting	±(MAX_STEPS x DCM_DELAY_STEP_MAX)	ps

Notes:

1. The values in this table are based on the operating conditions described in Table 53 and Table 58.
2. The maximum variable phase shift range, MAX_STEPS, is only valid when the DCM has no initial fixed-phase shifting, that is, the PHASE_SHIFT attribute is set to 0.
3. The DCM_DELAY_STEP values are provided at the end of Table 54.

Notes:

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage. These measurements include DCM CLK0 jitter.
2. IFF = Input Flip-Flop or Latch
3. Use IBIS to determine any duty-cycle distortion incurred using various standards.

Source-Synchronous Switching Characteristics

The parameters in this section provide the necessary values for calculating timing budgets for Spartan-6 FPGA source-synchronous transmitter and receiver data-valid windows.
