Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Quiescent Current

Typical values for quiescent supply current are specified at nominal voltage, 25°C junction temperatures (T_j). Quiescent supply current is specified by speed grade for Spartan-6 devices. Xilinx recommends analyzing static power consumption using the XPOWER™ Estimator (XPE) tool (download at <http://www.xilinx.com/power>) for conditions other than those specified in Table 5.

Table 5: Typical Quiescent Supply Current

Notes:

1. LVPECL_33 and TMDS_33 maximum V_{ICM} is the lower of V (maximum) or V_{CCAUX} – (V_{ID}/2)
2. When V_{CCAUX} = 3.3V, the DCD can be higher than 5% for V_{ICM} < 0.7V when using these I/O standards: LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, LVPECL_33, RSDS_25, RSDS_33, PPDS_25, and PPDS_33.
3. The -1L devices require V_{CCAUX} = 2.5V when using the LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, RSDS_25, RSDS_33, PPDS_25, and PPDS_33 I/O standards on inputs. LVPECL_33 is not supported in the -1L devices.

Notes:

- Delay depends on IODELAY2 tap setting. See TRACE report for actual values.
- Maximum delay = integer (number of taps/8) $\times$ T_{TAP8} + T_{TAPn} (where n equals the remainder). For minimum delay consult the TRACE setup and hold report. Minimum delay is typically greater than 30% of the maximum delay. Tap delays can vary by device and overall conditions. See TRACE report for actual values.
- Spartan-6 -1L devices only support tap 0. See TRACE report for actual values.

Table 54: Switching Characteristics for the Delay-Locked Loop (DLL)⁽¹⁾ (Cont'd)

Symbol	Description	Speed Grade								Units
		-3		-3N		-2		-1L		
		Min	Max	Min	Max	Min	Max	Min	Max	
LOCK_DLL ⁽³⁾	When using the DLL alone: The time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. When the DCM is locked, the CLKIN and CLKFB signals are in phase. CLKIN_FREQ_DLL < 50 MHz.	–	5	–	5	–	5	–	5	ms
	When using the DLL alone: The time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. When the DCM is locked, the CLKIN and CLKFB signals are in phase. CLKIN_FREQ_DLL > 50 MHz	–	0.60	–	0.60	–	0.60	–	0.60	ms
Delay Lines										
DCM_DELAY_STEP ⁽⁵⁾	Finest delay resolution, averaged over all steps.	10	40	10	40	10	40	10	40	ps

Notes:

1. The values in this table are based on the operating conditions described in Table 2 and Table 53.
2. Indicates the maximum amount of output jitter that the DCM adds to the jitter on the CLKIN input.
3. For optimal jitter tolerance and faster LOCK time, use the CLKIN_PERIOD attribute.
4. Some jitter and duty-cycle specifications include 1% of input clock period or 0.01 UI. For example, this data sheet specifies a maximum jitter of $\pm(1\% \text{ of CLKIN period} + 150 \text{ ps})$. Assuming that the CLKIN frequency is 100 MHz, the equivalent CLKIN period is 10 ns. Since 1% of 10 ns is 0.1 ns or 100 ps, the maximum jitter is $\pm(100 \text{ ps} + 150 \text{ ps}) = \pm250 \text{ ps}$.
5. A typical delay step size is 23 ps.
6. The timing analysis tools use the CLK_FEEDBACK = 1X condition for the CLKIN_CLKFB_PHASE value (reported as phase error). When using CLK_FEEDBACK = 2X, add 100 ps to the phase error for the CLKIN_CLKFB_PHASE value (as shown in this table).

CLKIN_CYC_JITT_FX_HF	Cycle-to-cycle jitter at the CLKIN input, based on CLKFX output frequency: FCLKFX > 150 MHz.	–	±150	–	±150	–	±150	–	±150	ps
CLKIN_PER_JITT_FX	Period jitter at the CLKIN input.	–	±1	–	±1	–	±1	–	±1	ns

Notes:

1. DFS specifications apply when using either of the DFS outputs (CLKFX or CLKFX180).
2. When using both DFS and DLL outputs on the same DCM, follow the more restrictive CLKIN_FREQ_DLL specifications in Table 53.
3. The CLKIN_DIVIDE_BY_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F_{MAX} (see Table 48 and Table 49 for BUFG and BUFGIO limits).
4. CLKIN input jitter beyond these limits can cause the DCM to lose LOCK.

LOCKED Time										
LOCK_FX ⁽²⁾	When FCLKIN < 50 MHz, the time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. The DFS asserts LOCKED when the CLKFX and CLKFX180 signals are valid. When using both the DLL and the DFS, use the longer locking time.	–	5	–	5	–	5	–	5	ms
	When FCLKIN > 50 MHz, the time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. The DFS asserts LOCKED when the CLKFX and CLKFX180 signals are valid. When using both the DLL and the DFS, use the longer locking time.	–	0.45	–	0.45	–	0.45	–	0.60	ms

Notes:

- The values in this table are based on the operating conditions described in Table 2 and Table 55.
- For optimal jitter tolerance and a faster LOCK time, use the CLKIN_PERIOD attribute.
- Output jitter is characterized with no input jitter. Output jitter strongly depends on the environment, including the number of SSOs, the output drive strength, CLB utilization, CLB switching activities, switching frequency, power supply, and PCB design. The actual maximum output jitter depends on the system application.
- The CLKFX, CLKFXDV, and CLKFX180 outputs have a duty cycle of approximately 50%.
- Some duty cycle and alignment specifications include a percentage of the CLKFX output period. For example, this data sheet specifies a maximum CLKFX jitter of $\pm(1\%$ of CLKFX period + 200 ps). Assuming that the CLKFX output frequency is 100 MHz, the equivalent CLKFX period is 10 ns, and 1% of 10 ns is 0.1 ns or 100 ps. Accordingly, the maximum jitter is $\pm(100\text{ ps} + 200\text{ ps}) = \pm 300\text{ ps}$.

Notes:

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage. These measurements include PLL CLKOUT0 jitter.
2. IFF = Input Flip-Flop or Latch
3. Use IBIS to determine any duty-cycle distortion incurred using various standards.

Notes:

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage. These measurements include CMT jitter; DCM CLK0 driving PLL, PLL CLKOUT0 driving BUFG.
2. IFF = Input Flip-Flop or Latch
3. Use IBIS to determine any duty-cycle distortion incurred using various standards.

Source-Synchronous Switching Characteristics
