### **Understanding Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

### **Applications of Embedded - FPGAs**

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

		LX150T	12.0	12.0	12.0	N/A	mA

**Notes:**

1. Typical values are specified at nominal voltage, 25°C junction temperatures ( $T_j$ ). Industrial (I) grade devices have the same typical values as commercial (C) grade devices at 25°C, but higher values at 100°C. Use the XPE tool to calculate 100°C values. Nominal  $V_{CCINT}$  is 1.20V; use the XPE tool to calculate 1.23V values for the nominal  $V_{CCINT}$  of the extended performance range.
2. Typical values are for blank configured devices with no output current loads, no active input pull-up resistors, all I/O pins are 3-state and floating.
3. If differential signaling is used, more accurate quiescent current estimates can be obtained by using the XPOWER Estimator (XPE) or XPOWER Analyzer (XPA) tools.

Table 6: Power Supply Ramp Time

Symbol	Description	Speed Grade	Ramp Time	Units
$V_{CCINTR}$	Internal supply voltage ramp time	-3, -3N, -2	0.20 to 50.0	ms
		-1L	0.20 to 40.0	ms
$V_{CCO2}$ <sup>(1)</sup>	Output drivers bank 2 supply voltage ramp time	All	0.20 to 50.0	ms
$V_{CCAU}$	Auxiliary supply voltage ramp time	All	0.20 to 50.0	ms

**Notes:**

1. The minimum  $V_{CCO2}$  for power-on reset and configuration is 1.65V.
2. Spartan-6 FPGAs require a certain amount of supply current during power-on to insure proper device initialization. The actual current consumed depends on the power-on ramp rate of the power supply. Use the XPOWER Estimator (XPE) or XPOWER Analyzer (XPA) tools to estimate current drain on these supplies. Spartan-6 devices do not have a required power-on sequence.

These are chosen to ensure that all standards meet their specifications. The selected standards are tested at a minimum  $V_{CCO}$  with the respective  $V_{OL}$  and  $V_{OH}$  voltage levels shown. Other standards are sample tested.

## Switching Characteristics

All values represented in this data sheet are based on these speed specifications: v1.20 for -3, -3N, and -2; and v1.08 for -1L. Switching characteristics are specified on a per-speed-grade basis and can be designated as Advance, Preliminary, or Production. Each designation is defined as follows:

### Advance

These specifications are based on simulations only and are typically available soon after device design specifications are frozen. Although speed grades with this designation are considered relatively stable and conservative, some under-reporting might still occur.

### Preliminary

These specifications are based on complete ES (engineering sample) silicon characterization. Devices and speed grades with this designation are intended to give a better indication of the expected performance of production silicon. The probability of under-reporting delays is greatly reduced as compared to Advance data.

### Production

These specifications are released once enough production silicon of a particular device family member has been characterized to provide full correlation between specifications and devices over numerous production lots. There is no under-reporting of delays, and customers receive formal notification of any subsequent changes. Typically, the slowest speed grades transition to Production before faster speed grades.

All specifications are always representative of worst-case supply voltage and junction temperature conditions.

Since individual family members are produced at different times, the migration from one category to another depends completely on the status of the fabrication process for each device.

The -1L speed grade refers to the lower-power Spartan-6 devices. The -3N speed grade refers to the Spartan-6 devices that do not support MCB functionality.

**Table 26** correlates the current status of each Spartan-6 device on a per speed grade basis.

## Testing of Switching Characteristics

All devices are 100% functionally tested. Internal timing parameters are derived from measuring internal test patterns. Listed below are representative values.

For more specific, more precise, and worst-case guaranteed data, use the values reported by the static timing analyzer and back-annotate to the simulation net list. Unless otherwise noted, values apply to all Spartan-6 devices.

**IOB Pad Input/Output/3-State Switching Characteristics**

**Table 28** (for commercial (XC) Spartan-6 devices) and **Table 29** (for Automotive XA Spartan-6 and Defense-grade Spartan-6Q devices) summarizes the values of standard-specific data input delays, output delays terminating at pads (based on standard), and 3-state delays.

- $T_{IOPI}$  is described as the delay from IOB pad through the input buffer to the I-pin of an IOB pad. The delay varies depending on the capability of the SelectIO input buffer.
- $T_{IOOP}$  is described as the delay from the O pin to the IOB pad through the output buffer of an IOB pad. The delay varies depending on the capability of the SelectIO output buffer.
- $T_{IOTP}$  is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is disabled. The delay varies depending on the SelectIO capability of the output buffer.

See the TRACE report for further information on delays when using an I/O standard with UNTUNED termination on inputs or outputs.

**Notes:**

- The values in this table are based on the operating conditions described in Table 2 and Table 53.
- Indicates the maximum amount of output jitter that the DCM adds to the jitter on the CLKIN input.
- For optimal jitter tolerance and faster LOCK time, use the CLKIN\_PERIOD attribute.
- Some jitter and duty-cycle specifications include 1% of input clock period or 0.01 UI. For example, this data sheet specifies a maximum jitter of  $\pm(1\% \text{ of CLKIN period} + 150 \text{ ps})$ . Assuming that the CLKIN frequency is 100 MHz, the equivalent CLKIN period is 10 ns. Since 1% of 10 ns is 0.1 ns or 100 ps, the maximum jitter is  $\pm(100 \text{ ps} + 150 \text{ ps}) = \pm250 \text{ ps}$ .
- A typical delay step size is 23 ps.
- The timing analysis tools use the CLK\_FEEDBACK = 1X condition for the CLKIN\_CLKFB\_PHASE value (reported as phase error). When using CLK\_FEEDBACK = 2X, add 100 ps to the phase error for the CLKIN\_CLKFB\_PHASE value (as shown in this table).

CLKIN_CYC_JITT_FX_HF	Cycle-to-cycle jitter at the CLKIN input, based on CLKFX output frequency: F <sub>CLKFX</sub> > 150 MHz.	—	$\pm 150$	—	$\pm 150$	—	$\pm 150$	—	$\pm 150$	ps	
CLKIN_PER_JITT_FX	Period jitter at the CLKIN input.	—	$\pm 1$	—	$\pm 1$	—	$\pm 1$	—	$\pm 1$	ns	

**Notes:**

- DFS specifications apply when using either of the DFS outputs (CLKFX or CLKFX180).
- When using both DFS and DLL outputs on the same DCM, follow the more restrictive CLKIN\_FREQ\_DLL specifications in Table 53.
- The CLKIN\_DIVIDE\_BY\_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F<sub>MAX</sub> (see Table 48 and Table 49 for BUFG and BUFI02 limits).
- CLKIN input jitter beyond these limits can cause the DCM to lose LOCK.

## Spartan-6 Device Pin-to-Pin Output Parameter Guidelines

All devices are 100% functionally tested. The representative values for typical pin locations and normal clock loading are listed in [Table 63](#) through [Table 69](#). Values are expressed in nanoseconds unless otherwise noted.

**Notes:**

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage. These measurements include PLL CLKOUT0 jitter.
2. IFF = Input Flip-Flop or Latch
3. Use IBIS to determine any duty-cycle distortion incurred using various standards.

- These values represent the worst-case skew between any two SelectIO resources in the package: shortest delay to longest delay from Pad to Ball.
- Some of the devices are available in both Pb and Pb-free (additional G) packages as standard ordering options. See [DS160: Spartan-6 Family Overview](#) for more information.

- This parameter indicates the total sampling error of Spartan-6 FPGA DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the DCM to capture the DDR input registers' edges of operation. These measurements include:
  - CLK0 DCM jitter
  - DCM accuracy (phase offset)
  - DCM phase shift resolution
 These measurements do not include package or clock tree skew.
