Understanding **Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Table 3: eFUSE Programming Conditions⁽¹⁾

Symbol	Description	Min	Typ	Max	Units
V_{FS} ⁽²⁾	External voltage supply	3.2	3.3	3.4	V
I_{FS}	V_{FS} supply current	–	–	40	mA
V_{CCAUX}	Auxiliary supply voltage relative to GND	3.2	3.3	3.45	V

V_{CCINT}	Internal supply voltage relative to GND	1.14	1.2	1.26	V

Notes:

1. These specifications apply during programming of the eFUSE AES key. Programming is only supported through JTAG. The AES key is only supported in the following devices: LX75, LX75T, LX100, LX100T, LX150, and LX150T.
2. When programming eFUSE, V_{FS} must be less than or equal to V_{CCAUX} . When not programming or when eFUSE is not used, Xilinx recommends connecting V_{FS} to GND. However, V_{FS} can be between GND and 3.45 V.
3. An R_{FUSE} resistor is required when programming the eFUSE AES key. When not programming or when eFUSE is not used, Xilinx recommends connecting the R_{FUSE} pin to V_{CCAUX} or GND. However, R_{FUSE} can be unconnected.

		LX9	2.5	2.5	2.5	2.5	mA
		LX16	3.0	3.0	3.0	3.0	mA
		LX25	4.0	4.0	4.0	4.0	mA
		LX25T	4.0	4.0	4.0	N/A	mA
		LX45	5.0	5.0	5.0	5.0	mA
		LX45T	5.0	5.0	5.0	N/A	mA
		LX75	7.0	7.0	7.0	7.0	mA
		LX75T	7.0	7.0	7.0	N/A	mA
		LX100	9.0	9.0	9.0	9.0	mA
		LX100T	9.0	9.0	9.0	N/A	mA
		LX150	12.0	12.0	12.0	12.0	mA
		LX150T	12.0	12.0	12.0	N/A	mA

Notes:

1. Typical values are specified at nominal voltage, 25°C junction temperatures (T_j). Industrial (I) grade devices have the same typical values as commercial (C) grade devices at 25°C, but higher values at 100°C. Use the XPE tool to calculate 100°C values. Nominal V_{CCINT} is 1.20V; use the XPE tool to calculate 1.23V values for the nominal V_{CCINT} of the extended performance range.
2. Typical values are for blank configured devices with no output current loads, no active input pull-up resistors, all I/O pins are 3-state and floating.
3. If differential signaling is used, more accurate quiescent current estimates can be obtained by using the XPOWER Estimator (XPE) or XPOWER Analyzer (XPA) tools.

Table 6: Power Supply Ramp Time

Symbol	Description	Speed Grade	Ramp Time	Units
V_{CCINTR}	Internal supply voltage ramp time	-3, -3N, -2	0.20 to 50.0	ms
		-1L	0.20 to 40.0	ms
V_{CCO2} ⁽¹⁾	Output drivers bank 2 supply voltage ramp time	All	0.20 to 50.0	ms
V_{CCAU}	Auxiliary supply voltage ramp time	All	0.20 to 50.0	ms

Notes:

1. The minimum V_{CCO2} for power-on reset and configuration is 1.65V.
2. Spartan-6 FPGAs require a certain amount of supply current during power-on to insure proper device initialization. The actual current consumed depends on the power-on ramp rate of the power supply. Use the XPOWER Estimator (XPE) or XPOWER Analyzer (XPA) tools to estimate current drain on these supplies. Spartan-6 devices do not have a required power-on sequence.

Output Delay Measurements

Output delays are measured using a Tektronix P6245 TDS500/600 probe (<1 pF) across approximately 4" of FR4 microstrip trace. Standard termination was used for all testing. The propagation delay of the 4" trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in [Figure 4](#) and [Figure 5](#).

[Figure 4: Single-Ended Test Setup](#)

[Figure 5: Differential Test Setup](#)

Measurements and test conditions are reflected in the IBIS models except where the IBIS format precludes it. Parameters V_{REF} , R_{REF} , C_{REF} , and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using the following method:

1. Simulate the output driver of choice into the generalized test setup, using values from [Table 32](#).
2. Record the time to V_{MEAS} .
3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS} .
5. Compare the results of steps 2 and 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

Notes:

1. SSO limits greater than the number of I/O per V_{CCO}/GND pair (Table 33) indicate No Limit for the given I/O standard. They are provided in this table to calculate limits when using multiple I/O standards in a bank.
2. Not available (N/A) indicates that the I/O standard is not available in the given bank.
3. When used with the MCB, these signals are exempt from SSO analysis due to the known activity of the MCB switching patterns. SSO performance is validated for all MCB instances. MCB outputs can, in some cases, exceed the SSO limits.

DCM_DELAY_STEP ⁽⁵⁾	Finest delay resolution, averaged over all steps.	10	40	10	40	10	40	10	40	ps	

Notes:

- The values in this table are based on the operating conditions described in Table 2 and Table 53.
- Indicates the maximum amount of output jitter that the DCM adds to the jitter on the CLKIN input.
- For optimal jitter tolerance and faster LOCK time, use the CLKIN_PERIOD attribute.
- Some jitter and duty-cycle specifications include 1% of input clock period or 0.01 UI. For example, this data sheet specifies a maximum jitter of $\pm(1\% \text{ of CLKIN period} + 150 \text{ ps})$. Assuming that the CLKIN frequency is 100 MHz, the equivalent CLKIN period is 10 ns. Since 1% of 10 ns is 0.1 ns or 100 ps, the maximum jitter is $\pm(100 \text{ ps} + 150 \text{ ps}) = \pm250 \text{ ps}$.
- A typical delay step size is 23 ps.
- The timing analysis tools use the CLK_FEEDBACK = 1X condition for the CLKIN_CLKFB_PHASE value (reported as phase error). When using CLK_FEEDBACK = 2X, add 100 ps to the phase error for the CLKIN_CLKFB_PHASE value (as shown in this table).

CLKIN_PER_JITT_FX	Period jitter at the CLKIN input.	—	± 1	—	± 1	—	± 1	—	± 1	ns	

Notes:

- DFS specifications apply when using either of the DFS outputs (CLKFX or CLKFX180).
- When using both DFS and DLL outputs on the same DCM, follow the more restrictive CLKIN_FREQ_DLL specifications in Table 53.
- The CLKIN_DIVIDE_BY_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F_{MAX} (see Table 48 and Table 49 for BUFG and BUFI02 limits).
- CLKIN input jitter beyond these limits can cause the DCM to lose LOCK.

- For optimal jitter tolerance and a faster LOCK time, use the CLKIN_PERIOD attribute.
- Output jitter is characterized with no input jitter. Output jitter strongly depends on the environment, including the number of SSOs, the output drive strength, CLB utilization, CLB switching activities, switching frequency, power supply, and PCB design. The actual maximum output jitter depends on the system application.
- The CLKFX, CLKFXDV, and CLKFX180 outputs have a duty cycle of approximately 50%.
- Some duty cycle and alignment specifications include a percentage of the CLKFX output period. For example, this data sheet specifies a maximum CLKFX jitter of ±(1% of CLKFX period + 200 ps). Assuming that the CLKFX output frequency is 100 MHz, the equivalent CLKFX period is 10 ns, and 1% of 10 ns is 0.1 ns or 100 ps. Accordingly, the maximum jitter is ±(100 ps + 200 ps) = ±300 ps.

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage.
2. IFF = Input Flip-Flop or Latch.

- This parameter indicates the total sampling error of Spartan-6 FPGA DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the DCM to capture the DDR input registers' edges of operation. These measurements include:
 - CLK0 DCM jitter
 - DCM accuracy (phase offset)
 - DCM phase shift resolution
 These measurements do not include package or clock tree skew.
