Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Notes:

1. All voltages are relative to ground.
2. See *Interface Performances for Memory Interfaces* in Table 25. The extended performance range is specified for designs not using the standard V_{CCINT} voltage range. The standard V_{CCINT} voltage range is used for:
 - Designs that do not use an MCB
 - LX4 devices
 - Devices in the TQG144 or CPG196 packages
 - Devices with the -3N speed grade
3. Recommended maximum voltage droop for V_{CCAUX} is 10 mV/ms.
4. During configuration, if V_{CCO_2} is 1.8V, then V_{CCAUX} must be 2.5V.
5. The -1L devices require $V_{CCAUX} = 2.5V$ when using the LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, RSDS_25, RSDS_33, PPDS_25, and PPDS_33 I/O standards on inputs. LVPECL_33 is not supported in the -1L devices.
6. Configuration data is retained even if V_{CCO} drops to 0V.
7. Includes V_{CCO} of 1.2V, 1.5V, 1.8V, 2.5V, and 3.3V.
8. For PCI systems, the transmitter and receiver should have common supplies for V_{CCO} .
9. Devices with a -1L speed grade do not support Xilinx PCI IP.
10. Do not exceed a total of 100 mA per bank.
11. V_{BATT} is required to maintain the battery backed RAM (BBR) AES key when V_{CCAUX} is not applied. Once V_{CCAUX} is applied, V_{BATT} can be unconnected. When BBR is not used, Xilinx recommends connecting to V_{CCAUX} or GND. However, V_{BATT} can be unconnected.

2. Measurements are made at typical, minimum, and maximum V_{REF} values. Reported delays reflect worst case of these measurements. V_{REF} values listed are typical.
3. Input voltage level from which measurement starts.
4. This is an input voltage reference that bears no relation to the V_{REF} / V_{MEAS} parameters found in IBIS models and/or noted in [Figure 4](#).
5. The value given is the differential input voltage.

Output Delay Measurements

Output delays are measured using a Tektronix P6245 TDS500/600 probe (<1 pF) across approximately 4" of FR4 microstrip trace. Standard termination was used for all testing. The propagation delay of the 4" trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in [Figure 4](#) and [Figure 5](#).

[Figure 4: Single-Ended Test Setup](#)

[Figure 5: Differential Test Setup](#)

Measurements and test conditions are reflected in the IBIS models except where the IBIS format precludes it. Parameters V_{REF} , R_{REF} , C_{REF} , and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using the following method:

1. Simulate the output driver of choice into the generalized test setup, using values from [Table 32](#).
2. Record the time to V_{MEAS} .
3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS} .
5. Compare the results of steps 2 and 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

Simultaneously Switching Outputs

Due to package electrical parasitics, a given package supports a limited number of simultaneous switching outputs (SSOs) when using fast, high-drive outputs. [Table 33](#) and [Table 34](#) provide guidelines for the recommended maximum allowable number of SSOs. These guidelines describe the maximum number of user I/O pins of an output signal standard that should simultaneously switch in the same direction, while maintaining a safe level of switching noise for that particular signal standard. Meeting these guidelines for the stated test conditions ensures that the FPGA operates free from the adverse effects of GND and power bounce.

For each device/package combination, [Table 33](#) provides the number of equivalent V_{CCO}/GND pairs per bank. For each output signal standard and drive strength, [Table 34](#) recommends the maximum number of SSOs, switching in the same direction, allowed per V_{CCO}/GND pair within an I/O bank. The guidelines are categorized by package style, slew rate, and output drive current. The number of SSOs are also specified by I/O bank. Multiply the appropriate numbers from each table to calculate the maximum number of SSOs allowed within an I/O bank. The guidelines assume that all pins within a bank use the same I/O standard. Exceeding these SSO guidelines can result in increased power or GND bounce, degraded signal integrity, or increased system jitter. For a given I/O standard, if the SSO limit per pair in [Table 34](#) is greater than the maximum I/O per pair in [Table 33](#), then there is no SSO limit for the exclusive use of that I/O standard.

The recommended maximum SSO values assume that the FPGA is soldered on a printed circuit board and that the board uses sound design practices. Due to the additional inductance introduced by the socket, the SSO values do not apply for FPGAs mounted in sockets. The SSO values assume that the V_{CCAUX} is powered at 3.3V. Setting V_{CCAUX} to 2.5V provides better SSO characteristics. For more detail, see [UG381: Spartan-6 FPGA SelectIO Resources User Guide](#).

CLKFB_DELAY_VAR_EXT	Allowable variation of the off-chip feedback delay from the DCM output to the CLKFB input.	–	±1	–	±1	–	±1	–	±1	ns	

Notes:

1. DLL specifications apply when using any of the DLL outputs: CLK0, CLK90, CLK180, CLK270, CLK2X, CLK2X180, or CLKDV.
2. When operating independently of the DLL, the DFS supports lower CLKIN_FREQ_DLL frequencies. See Table 55.
3. The CLKIN_DIVIDE_BY_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F_{MAX} (see Table 48 and Table 49 for BUFG and BUFIO2 limits). When used with CLK_FEEDBACK=2X, the input clock frequency matches the frequency for CLK2X, and is limited to CLKOUT_FREQ_2X.
4. CLKIN_FREQ_DLL input jitter beyond these limits can cause the DCM to lose LOCK, indicated by the LOCKED output deasserting. The user must then reset the DCM.
5. When using both DCMs in a CMT, both DCMs must be LOCKED.

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage. These measurements include DCM CLK0 jitter.
2. IFF = Input Flip-Flop or Latch
3. Use IBIS to determine any duty-cycle distortion incurred using various standards.

Notes:

- These values represent the worst-case skew between any two SelectIO resources in the package: shortest delay to longest delay from Pad to Ball.
- Some of the devices are available in both Pb and Pb-free (additional G) packages as standard ordering options. See [DS160: Spartan-6 Family Overview](#) for more information.

Table 80: Sample Window

Symbol	Description	Device ⁽¹⁾	Speed Grade				Units
			-3	-3N	-2	-1L	
T_{SAMP}	Sampling Error at Receiver Pins ⁽²⁾	All	510	510	530	740	ps
T_{SAMP_BUFIO2}	Sampling Error at Receiver Pins using BUFIO2 ⁽³⁾	All	430	430	450	590	ps

Notes:

- LXT devices are not available with a -1L speed grade.
- This parameter indicates the total sampling error of Spartan-6 FPGA DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the DCM to capture the DDR input registers' edges of operation. These measurements include:
 - CLK0 DCM jitter
 - DCM accuracy (phase offset)
 - DCM phase shift resolution
 These measurements do not include package or clock tree skew.
- This parameter indicates the total sampling error of Spartan-6 FPGA DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the BUFI02 clock network and IODELAY2 to capture the DDR input registers' edges of operation. These measurements do not include package or clock tree skew.
