Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Notes:

- All voltages are relative to ground.
- See *Interface Performances for Memory Interfaces* in Table 25. The extended performance range is specified for designs not using the standard V_{CCINT} voltage range. The standard V_{CCINT} voltage range is used for:
 - Designs that do not use an MCB
 - LX4 devices
 - Devices in the TQG144 or CPG196 packages
 - Devices with the -3N speed grade
- Recommended maximum voltage droop for V_{CCAUX} is 10 mV/ms.
- During configuration, if V_{CCO_2} is 1.8V, then V_{CCAUX} must be 2.5V.
- The -1L devices require $V_{CCAUX} = 2.5V$ when using the LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, RSDS_25, RSDS_33, PPDS_25, and PPDS_33 I/O standards on inputs. LVPECL_33 is not supported in the -1L devices.
- Configuration data is retained even if V_{CCO} drops to 0V.
- Includes V_{CCO} of 1.2V, 1.5V, 1.8V, 2.5V, and 3.3V.
- For PCI systems, the transmitter and receiver should have common supplies for V_{CCO} .
- Devices with a -1L speed grade do not support Xilinx PCI IP.
- Do not exceed a total of 100 mA per bank.
- V_{BATT} is required to maintain the battery backed RAM (BBR) AES key when V_{CCAUX} is not applied. Once V_{CCAUX} is applied, V_{BATT} can be unconnected. When BBR is not used, Xilinx recommends connecting to V_{CCAUX} or GND. However, V_{BATT} can be unconnected.

		LX25	4.0	4.0	4.0	4.0	mA
		LX25T	4.0	4.0	4.0	N/A	mA
		LX45	5.0	5.0	5.0	5.0	mA
		LX45T	5.0	5.0	5.0	N/A	mA
		LX75	7.0	7.0	7.0	7.0	mA
		LX75T	7.0	7.0	7.0	N/A	mA
		LX100	9.0	9.0	9.0	9.0	mA
		LX100T	9.0	9.0	9.0	N/A	mA
		LX150	12.0	12.0	12.0	12.0	mA
		LX150T	12.0	12.0	12.0	N/A	mA

Notes:

- Typical values are specified at nominal voltage, 25°C junction temperatures (T_j). Industrial (I) grade devices have the same typical values as commercial (C) grade devices at 25°C, but higher values at 100°C. Use the XPE tool to calculate 100°C values. Nominal V_{CCINT} is 1.20V; use the XPE tool to calculate 1.23V values for the nominal V_{CCINT} of the extended performance range.
- Typical values are for blank configured devices with no output current loads, no active input pull-up resistors, all I/O pins are 3-state and floating.
- If differential signaling is used, more accurate quiescent current estimates can be obtained by using the XPOWER Estimator (XPE) or XPOWER Analyzer (XPA) tools.

Table 6: Power Supply Ramp Time

Symbol	Description	Speed Grade	Ramp Time	Units
V _{CCINTR}	Internal supply voltage ramp time	-3, -3N, -2	0.20 to 50.0	ms
		-1L	0.20 to 40.0	ms
V _{CCO2} ⁽¹⁾	Output drivers bank 2 supply voltage ramp time	All	0.20 to 50.0	ms
V _{CCAUXR}	Auxiliary supply voltage ramp time	All	0.20 to 50.0	ms

Notes:

- The minimum V_{CCO2} for power-on reset and configuration is 1.65V.
- Spartan-6 FPGAs require a certain amount of supply current during power-on to insure proper device initialization. The actual current consumed depends on the power-on ramp rate of the power supply. Use the XPOWER Estimator (XPE) or XPOWER Analyzer (XPA) tools to estimate current drain on these supplies. Spartan-6 devices do not have a required power-on sequence.

IOB Pad Input/Output/3-State Switching Characteristics

[Table 28](#) (for commercial (XC) Spartan-6 devices) and [Table 29](#) (for Automotive XA Spartan-6 and Defense-grade Spartan-6Q devices) summarizes the values of standard-specific data input delays, output delays terminating at pads (based on standard), and 3-state delays.

- T_{IOPI} is described as the delay from IOB pad through the input buffer to the I-pin of an IOB pad. The delay varies depending on the capability of the SelectIO input buffer.
- T_{IOOP} is described as the delay from the O pin to the IOB pad through the output buffer of an IOB pad. The delay varies depending on the capability of the SelectIO output buffer.
- T_{IOTP} is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is disabled. The delay varies depending on the SelectIO capability of the output buffer.

See the TRACE report for further information on delays when using an I/O standard with UNTUNED termination on inputs or outputs.

Output Delay Measurements

Output delays are measured using a Tektronix P6245 TDS500/600 probe (< 1 pF) across approximately 4" of FR4 microstrip trace. Standard termination was used for all testing. The propagation delay of the 4" trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in Figure 4 and Figure 5.

Figure 4: Single-Ended Test Setup

ds162_07_011309

Figure 5: Differential Test Setup

Measurements and test conditions are reflected in the IBIS models except where the IBIS format precludes it. Parameters V_{REF} , R_{REF} , C_{REF} , and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using the following method:

1. Simulate the output driver of choice into the generalized test setup, using values from Table 32.
2. Record the time to V_{MEAS} .
3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS} .
5. Compare the results of steps 2 and 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

Delay Lines										
DCM_DELAY_STEP ⁽⁵⁾	Finest delay resolution, averaged over all steps.	10	40	10	40	10	40	10	40	ps

Notes:

1. The values in this table are based on the operating conditions described in Table 2 and Table 53.
2. Indicates the maximum amount of output jitter that the DCM adds to the jitter on the CLKIN input.
3. For optimal jitter tolerance and faster LOCK time, use the CLKIN_PERIOD attribute.
4. Some jitter and duty-cycle specifications include 1% of input clock period or 0.01 UI. For example, this data sheet specifies a maximum jitter of $\pm(1\% \text{ of CLKIN period} + 150 \text{ ps})$. Assuming that the CLKIN frequency is 100 MHz, the equivalent CLKIN period is 10 ns. Since 1% of 10 ns is 0.1 ns or 100 ps, the maximum jitter is $\pm(100 \text{ ps} + 150 \text{ ps}) = \pm250 \text{ ps}$.
5. A typical delay step size is 23 ps.
6. The timing analysis tools use the CLK_FEEDBACK = 1X condition for the CLKIN_CLKFB_PHASE value (reported as phase error). When using CLK_FEEDBACK = 2X, add 100 ps to the phase error for the CLKIN_CLKFB_PHASE value (as shown in this table).

CLKIN_CYC_JITT_FX_HF	Cycle-to-cycle jitter at the CLKIN input, based on CLKFX output frequency: FCLKFX > 150 MHz.	–	±150	–	±150	–	±150	–	±150	ps
CLKIN_PER_JITT_FX	Period jitter at the CLKIN input.	–	±1	–	±1	–	±1	–	±1	ns

Notes:

1. DFS specifications apply when using either of the DFS outputs (CLKFX or CLKFX180).
2. When using both DFS and DLL outputs on the same DCM, follow the more restrictive CLKIN_FREQ_DLL specifications in Table 53.
3. The CLKIN_DIVIDE_BY_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F_{MAX} (see Table 48 and Table 49 for BUFG and BUFGIO limits).
4. CLKIN input jitter beyond these limits can cause the DCM to lose LOCK.

	When CLKIN ≥ 60 MHz, the maximum allowed number of DCM_DELAY_STEP steps for a given CLKIN clock period, where T = CLKIN clock period in ns. When using CLKIN_DIVIDE_BY_2 = TRUE, double the clock-effective clock period.	$\pm(\text{INTEGER}(15 \times (\text{TCLKIN} - 3 \text{ ns})))$	steps

Notes:

- The values in this table are based on the operating conditions described in Table 53 and Table 58.
- The maximum variable phase shift range, MAX_STEPS, is only valid when the DCM has no initial fixed-phase shifting, that is, the PHASE_SHIFT attribute is set to 0.
- The DCM_DELAY_STEP values are provided at the end of Table 54.

Notes:

1. Setup and Hold times are measured over worst case conditions (process, voltage, temperature). Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage. These measurements include PLL CLKOUT0 jitter.
2. IFF = Input Flip-Flop or Latch
3. Use IBIS to determine any duty-cycle distortion incurred using various standards.
