Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Notes:

1. All voltages are relative to ground.
2. See *Interface Performances for Memory Interfaces* in Table 25. The extended performance range is specified for designs not using the standard V_{CCINT} voltage range. The standard V_{CCINT} voltage range is used for:
 - Designs that do not use an MCB
 - LX4 devices
 - Devices in the TQG144 or CPG196 packages
 - Devices with the -3N speed grade
3. Recommended maximum voltage droop for V_{CCAUX} is 10 mV/ms.
4. During configuration, if V_{CCO_2} is 1.8V, then V_{CCAUX} must be 2.5V.
5. The -1L devices require $V_{CCAUX} = 2.5V$ when using the LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, RSDS_25, RSDS_33, PPDS_25, and PPDS_33 I/O standards on inputs. LVPECL_33 is not supported in the -1L devices.
6. Configuration data is retained even if V_{CCO} drops to 0V.
7. Includes V_{CCO} of 1.2V, 1.5V, 1.8V, 2.5V, and 3.3V.
8. For PCI systems, the transmitter and receiver should have common supplies for V_{CCO} .
9. Devices with a -1L speed grade do not support Xilinx PCI IP.
10. Do not exceed a total of 100 mA per bank.
11. V_{BATT} is required to maintain the battery backed RAM (BBR) AES key when V_{CCAUX} is not applied. Once V_{CCAUX} is applied, V_{BATT} can be unconnected. When BBR is not used, Xilinx recommends connecting to V_{CCAUX} or GND. However, V_{BATT} can be unconnected.

IOB Pad Input/Output/3-State Switching Characteristics

Table 28 (for commercial (XC) Spartan-6 devices) and **Table 29** (for Automotive XA Spartan-6 and Defense-grade Spartan-6Q devices) summarizes the values of standard-specific data input delays, output delays terminating at pads (based on standard), and 3-state delays.

- T_{IOP} is described as the delay from IOB pad through the input buffer to the I-pin of an IOB pad. The delay varies depending on the capability of the SelectIO input buffer.
- T_{IOOP} is described as the delay from the O pin to the IOB pad through the output buffer of an IOB pad. The delay varies depending on the capability of the SelectIO output buffer.
- T_{IOTP} is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is disabled. The delay varies depending on the SelectIO capability of the output buffer.

See the TRACE report for further information on delays when using an I/O standard with UNTUNED termination on inputs or outputs.

Notes:

1. Input waveform switches between V_L and V_H .
2. Measurements are made at typical, minimum, and maximum V_{REF} values. Reported delays reflect worst case of these measurements. V_{REF} values listed are typical.
3. Input voltage level from which measurement starts.
4. This is an input voltage reference that bears no relation to the V_{REF} / V_{MEAS} parameters found in IBIS models and/or noted in [Figure 4](#).
5. The value given is the differential input voltage.

Output Delay Measurements

Output delays are measured using a Tektronix P6245 TDS500/600 probe (<1 pF) across approximately 4" of FR4 microstrip trace. Standard termination was used for all testing. The propagation delay of the 4" trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in [Figure 4](#) and [Figure 5](#).

[Figure 4: Single-Ended Test Setup](#)

[Figure 5: Differential Test Setup](#)

Measurements and test conditions are reflected in the IBIS models except where the IBIS format precludes it. Parameters V_{REF} , R_{REF} , C_{REF} , and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using the following method:

1. Simulate the output driver of choice into the generalized test setup, using values from [Table 32](#).
2. Record the time to V_{MEAS} .
3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS} .
5. Compare the results of steps 2 and 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

F_{PFDMIN}	Minimum Frequency at the Phase Frequency Detector	LX devices	19	19	19	19	MHz
		LXT devices	19	19	19	N/A	MHz
$T_{FBDELAY}$	Maximum Delay in the Feedback Path	All	3 ns Max or one CLKIN cycle				

Notes:

1. LXT devices are not available with a -1L speed grade.
2. Values for this parameter are available in the Clocking Wizard.
3. The PLL does not filter typical spread spectrum input clocks because they are usually far below the bandwidth filter frequencies.
4. Includes global clock buffer.
5. Calculated as $F_{VCO}/128$ assuming output duty cycle is 50%.
6. When using CLK_FEEDBACK = CLKOUT0 with BUFI02 feedback, the feedback frequency will be higher than the phase frequency detector frequency. $F_{PFDMAX} = F_{CLKFB} / CLKFBOUT_MULT$

Setup time is measured relative to the Global Clock input signal using the slowest process, highest temperature, and lowest voltage. Hold time is measured relative to the Global Clock input signal using the fastest process, lowest temperature, and highest voltage.
2. Default delay uses IODELAY2 tap 0.
3. IFF = Input Flip-Flop or Latch.
