Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Notes:

1. LVPECL_33 and TMDS_33 maximum V_{ICM} is the lower of V (maximum) or V_{CCAUX} – (V_{ID}/2)
2. When V_{CCAUX} = 3.3V, the DCD can be higher than 5% for V_{ICM} < 0.7V when using these I/O standards: LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, LVPECL_33, RSDS_25, RSDS_33, PPDS_25, and PPDS_33.
3. The -1L devices require V_{CCAUX} = 2.5V when using the LVDS_25, LVDS_33, BLVDS_25, LVPECL_25, RSDS_25, RSDS_33, PPDS_25, and PPDS_33 I/O standards on inputs. LVPECL_33 is not supported in the -1L devices.

Switching Characteristics

All values represented in this data sheet are based on these speed specifications: v1.20 for -3, -3N, and -2; and v1.08 for -1L. Switching characteristics are specified on a per-speed-grade basis and can be designated as Advance, Preliminary, or Production. Each designation is defined as follows:

Advance

These specifications are based on simulations only and are typically available soon after device design specifications are frozen. Although speed grades with this designation are considered relatively stable and conservative, some under-reporting might still occur.

Preliminary

These specifications are based on complete ES (engineering sample) silicon characterization. Devices and speed grades with this designation are intended to give a better indication of the expected performance of production silicon. The probability of under-reporting delays is greatly reduced as compared to Advance data.

Production

These specifications are released once enough production silicon of a particular device family member has been characterized to provide full correlation between specifications and devices over numerous production lots. There is no under-reporting of delays, and customers receive formal notification of any subsequent changes. Typically, the slowest speed grades transition to Production before faster speed grades.

All specifications are always representative of worst-case supply voltage and junction temperature conditions.

Since individual family members are produced at different times, the migration from one category to another depends completely on the status of the fabrication process for each device.

The -1L speed grade refers to the lower-power Spartan-6 devices. The -3N speed grade refers to the Spartan-6 devices that do not support MCB functionality.

[Table 26](#) correlates the current status of each Spartan-6 device on a per speed grade basis.

Testing of Switching Characteristics

All devices are 100% functionally tested. Internal timing parameters are derived from measuring internal test patterns. Listed below are representative values.

For more specific, more precise, and worst-case guaranteed data, use the values reported by the static timing analyzer and back-annotate to the simulation net list. Unless otherwise noted, values apply to all Spartan-6 devices.

IOB Pad Input/Output/3-State Switching Characteristics

[Table 28](#) (for commercial (XC) Spartan-6 devices) and [Table 29](#) (for Automotive XA Spartan-6 and Defense-grade Spartan-6Q devices) summarizes the values of standard-specific data input delays, output delays terminating at pads (based on standard), and 3-state delays.

- T_{IOPI} is described as the delay from IOB pad through the input buffer to the I-pin of an IOB pad. The delay varies depending on the capability of the SelectIO input buffer.
- T_{IOOP} is described as the delay from the O pin to the IOB pad through the output buffer of an IOB pad. The delay varies depending on the capability of the SelectIO output buffer.
- T_{IOTP} is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is disabled. The delay varies depending on the SelectIO capability of the output buffer.

See the TRACE report for further information on delays when using an I/O standard with UNTUNED termination on inputs or outputs.

Notes:

1. The Spartan-6Q FPGA -1L values are listed in Table 28.

Table 30 summarizes the value of T_{IOTPHZ}. T_{IOTPHZ} is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is enabled (i.e., a high impedance state). These delays are measured using LVC MOS25, Fast, 12 mA.

Output Delay Measurements

Output delays are measured using a Tektronix P6245 TDS500/600 probe (< 1 pF) across approximately 4" of FR4 microstrip trace. Standard termination was used for all testing. The propagation delay of the 4" trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in Figure 4 and Figure 5.

Figure 4: Single-Ended Test Setup

ds162_07_011309

Figure 5: Differential Test Setup

Measurements and test conditions are reflected in the IBIS models except where the IBIS format precludes it. Parameters V_{REF} , R_{REF} , C_{REF} , and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using the following method:

1. Simulate the output driver of choice into the generalized test setup, using values from Table 32.
2. Record the time to V_{MEAS} .
3. Simulate the output driver of choice into the actual PCB trace and load, using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS} .
5. Compare the results of steps 2 and 4. The increase or decrease in delay yields the actual propagation delay of the PCB trace.

Simultaneously Switching Outputs

Due to package electrical parasitics, a given package supports a limited number of simultaneous switching outputs (SSOs) when using fast, high-drive outputs. [Table 33](#) and [Table 34](#) provide guidelines for the recommended maximum allowable number of SSOs. These guidelines describe the maximum number of user I/O pins of an output signal standard that should simultaneously switch in the same direction, while maintaining a safe level of switching noise for that particular signal standard. Meeting these guidelines for the stated test conditions ensures that the FPGA operates free from the adverse effects of GND and power bounce.

For each device/package combination, [Table 33](#) provides the number of equivalent V_{CCO} /GND pairs per bank. For each output signal standard and drive strength, [Table 34](#) recommends the maximum number of SSOs, switching in the same direction, allowed per V_{CCO} /GND pair within an I/O bank. The guidelines are categorized by package style, slew rate, and output drive current. The number of SSOs are also specified by I/O bank. Multiply the appropriate numbers from each table to calculate the maximum number of SSOs allowed within an I/O bank. The guidelines assume that all pins within a bank use the same I/O standard. Exceeding these SSO guidelines can result in increased power or GND bounce, degraded signal integrity, or increased system jitter. For a given I/O standard, if the SSO limit per pair in [Table 34](#) is greater than the maximum I/O per pair in [Table 33](#), then there is no SSO limit for the exclusive use of that I/O standard.

The recommended maximum SSO values assume that the FPGA is soldered on a printed circuit board and that the board uses sound design practices. Due to the additional inductance introduced by the socket, the SSO values do not apply for FPGAs mounted in sockets. The SSO values assume that the V_{CCAUX} is powered at 3.3V. Setting V_{CCAUX} to 2.5V provides better SSO characteristics. For more detail, see [UG381](#): *Spartan-6 FPGA SelectIO Resources User Guide*.

Notes:

- DLL specifications apply when using any of the DLL outputs: CLK0, CLK90, CLK180, CLK270, CLK2X, CLK2X180, or CLKDV.
- When operating independently of the DLL, the DFS supports lower CLKIN_FREQ_DLL frequencies. See Table 55.
- The CLKIN_DIVIDE_BY_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F_{MAX} (see Table 48 and Table 49 for BUFG and BUFGIO2 limits). When used with CLK_FEEDBACK=2X, the input clock frequency matches the frequency for CLK2X, and is limited to CLKOUT_FREQ_2X.
- CLKIN_FREQ_DLL input jitter beyond these limits can cause the DCM to lose LOCK, indicated by the LOCKED output deasserting. The user must then reset the DCM.
- When using both DCMs in a CMT, both DCMs must be LOCKED.

LOCK_DLL ⁽³⁾	When using the DLL alone: The time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. When the DCM is locked, the CLKIN and CLKFB signals are in phase. CLKIN_FREQ_DLL < 50 MHz.	–	5	–	5	–	5	–	5	ms
	When using the DLL alone: The time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. When the DCM is locked, the CLKIN and CLKFB signals are in phase. CLKIN_FREQ_DLL > 50 MHz	–	0.60	–	0.60	–	0.60	–	0.60	ms
Delay Lines										
DCM_DELAY_STEP ⁽⁵⁾	Finest delay resolution, averaged over all steps.	10	40	10	40	10	40	10	40	ps

Notes:

1. The values in this table are based on the operating conditions described in Table 2 and Table 53.
2. Indicates the maximum amount of output jitter that the DCM adds to the jitter on the CLKIN input.
3. For optimal jitter tolerance and faster LOCK time, use the CLKIN_PERIOD attribute.
4. Some jitter and duty-cycle specifications include 1% of input clock period or 0.01 UI. For example, this data sheet specifies a maximum jitter of $\pm(1\% \text{ of CLKIN period} + 150 \text{ ps})$. Assuming that the CLKIN frequency is 100 MHz, the equivalent CLKIN period is 10 ns. Since 1% of 10 ns is 0.1 ns or 100 ps, the maximum jitter is $\pm(100 \text{ ps} + 150 \text{ ps}) = \pm 250 \text{ ps}$.
5. A typical delay step size is 23 ps.
6. The timing analysis tools use the CLK_FEEDBACK = 1X condition for the CLKIN_CLKFB_PHASE value (reported as phase error). When using CLK_FEEDBACK = 2X, add 100 ps to the phase error for the CLKIN_CLKFB_PHASE value (as shown in this table).

CLKIN_PER_JITT_FX	Period jitter at the CLKIN input.	–	±1	–	±1	–	±1	–	±1	ns

Notes:

1. DFS specifications apply when using either of the DFS outputs (CLKFX or CLKFX180).
2. When using both DFS and DLL outputs on the same DCM, follow the more restrictive CLKIN_FREQ_DLL specifications in Table 53.
3. The CLKIN_DIVIDE_BY_2 attribute increases the effective input frequency range. When set to TRUE, the input clock frequency is divided by two as it enters the DCM. Input clock frequencies for the clock buffer being used can be increased up to the F_{MAX} (see Table 48 and Table 49 for BUFG and BUFGIO limits).
4. CLKIN input jitter beyond these limits can cause the DCM to lose LOCK.

	When FCLKIN > 50 MHz, the time from deassertion at the DCM's reset input to the rising transition at its LOCKED output. The DFS asserts LOCKED when the CLKFX and CLKFX180 signals are valid. When using both the DLL and the DFS, use the longer locking time.	–	0.45	–	0.45	–	0.45	–	0.60	ms

Notes:

- The values in this table are based on the operating conditions described in Table 2 and Table 55.
- For optimal jitter tolerance and a faster LOCK time, use the CLKIN_PERIOD attribute.
- Output jitter is characterized with no input jitter. Output jitter strongly depends on the environment, including the number of SSOs, the output drive strength, CLB utilization, CLB switching activities, switching frequency, power supply, and PCB design. The actual maximum output jitter depends on the system application.
- The CLKFX, CLKFXDV, and CLKFX180 outputs have a duty cycle of approximately 50%.
- Some duty cycle and alignment specifications include a percentage of the CLKFX output period. For example, this data sheet specifies a maximum CLKFX jitter of $\pm(1\%$ of CLKFX period + 200 ps). Assuming that the CLKFX output frequency is 100 MHz, the equivalent CLKFX period is 10 ns, and 1% of 10 ns is 0.1 ns or 100 ps. Accordingly, the maximum jitter is $\pm(100\text{ ps} + 200\text{ ps}) = \pm 300\text{ ps}$.

- Output jitter is characterized with no input jitter. Output jitter strongly depends on the environment, including the number of SSOs, the output drive strength, CLB utilization, CLB switching activities, switching frequency, power supply, and PCB design. The actual maximum output jitter depends on the system application.
- The CLKFX, CLKFXDV, and CLKFX180 outputs have a duty cycle of approximately 50%.
- Some duty-cycle and alignment specifications include a percentage of the CLKFX output period. For example, this data sheet specifies a maximum CLKFX jitter of $\pm(1\% \text{ of CLKFX period} + 200 \text{ ps})$. Assuming that the CLKFX output frequency is 100 MHz, the equivalent CLKFX period is 10 ns, and 1% of 10 ns is 0.1 ns or 100 ps. Accordingly, the maximum jitter is $\pm(100 \text{ ps} + 200 \text{ ps}) = \pm 300 \text{ ps}$.
- When using CENTER_LOW_SPREAD, CENTER_HIGH_SPREAD, the valid values for CLKFX_MULTIPLY are limited to 2 through 32, and the valid values for CLKFX_DIVIDE are limited to 1 through 4.

Notes:

- The values in this table are based on the operating conditions described in Table 53 and Table 58.
- The maximum variable phase shift range, MAX_STEPS, is only valid when the DCM has no initial fixed-phase shifting, that is, the PHASE_SHIFT attribute is set to 0.
- The DCM_DELAY_STEP values are provided at the end of Table 54.
