Welcome to E-XFL.COM

Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Active
Number of LABs/CLBs	-
Number of Logic Elements/Cells	2304
Total RAM Bits	18432
Number of I/O	114
Number of Gates	50000
Voltage - Supply	3V ~ 3.6V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 85°C (TC)
Package / Case	144-LQFP
Supplier Device Package	144-LQFP (20x20)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/at40k40al-1bqi

Cache Logic Design

The AT40KAL, AT6000 and FPSLIC families are capable of implementing Cache Logic (dynamic full/partial logic reconfiguration, without loss of data, on-the-fly) for building adaptive logic and systems. As new logic functions are required, they can be loaded into the logic cache without losing the data already there or disrupting the operation of the rest of the chip; replacing or complementing the active logic. The AT40KAL can act as a reconfigurable coprocessor.

Automatic Component Generators

The AT40KAL FPGA family is capable of implementing user-defined, automatically generated, macros in multiple designs; speed and functionality are unaffected by the macro orientation or density of the target device. This enables the fastest, most predictable and efficient FPGA design approach and minimizes design risk by reusing already proven functions. The Automatic Component Generators work seamlessly with industry standard schematic and synthesis tools to create the fastest, most efficient designs available.

The patented AT40KAL series architecture employs a symmetrical grid of small yet powerful cells connected to a flexible busing network. Independently controlled clocks and resets govern every column of cells. The array is surrounded by programmable I/O.

Devices range in size from 5,000 to 50,000 usable gates in the family, and have 256 to 3,048 registers. Pin locations are consistent throughout the AT40KAL series for easy design migration in the same package footprint. The AT40KAL series FPGAs utilize a reliable 0.35µ triple-metal, CMOS process and are 100% factory-tested. Atmel's PC- and workstation-based integrated development system (IDS) is used to create AT40KAL series designs. Multiple design entry methods are supported.

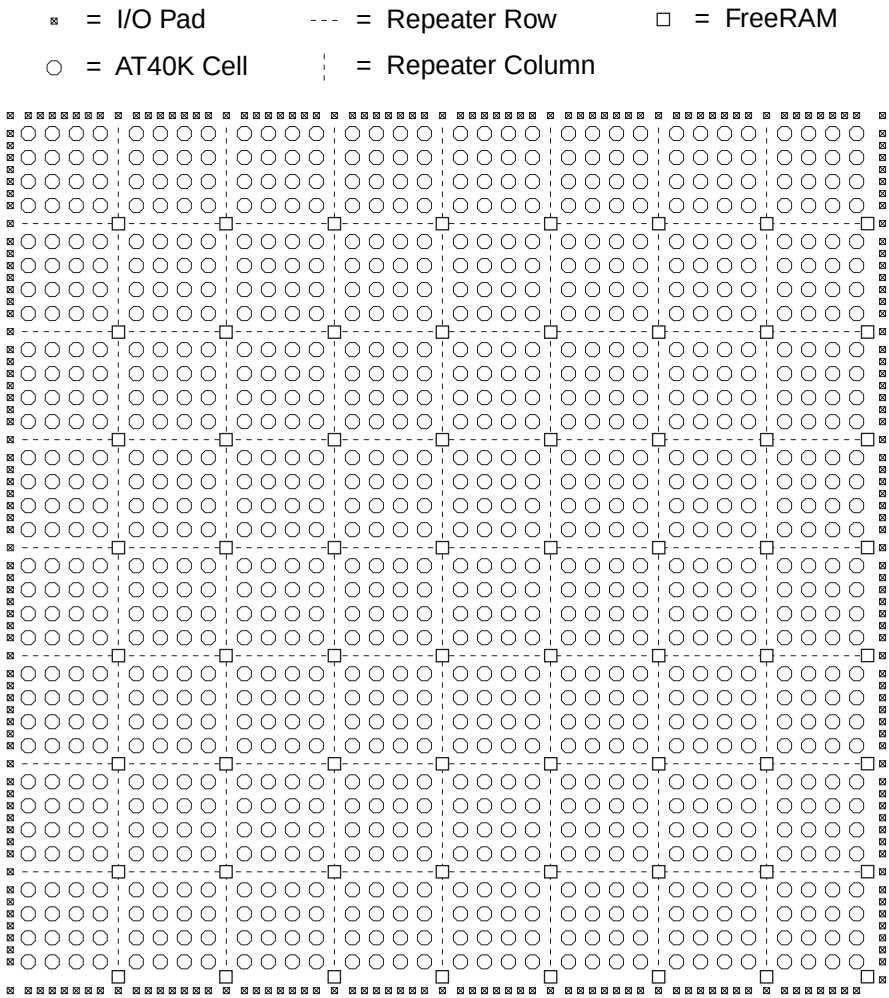
The Atmel architecture was developed to provide the highest levels of performance, functional density and design flexibility in an FPGA. The cells in the Atmel array are small, efficient and can implement any pair of Boolean functions of (the same) three inputs or any single Boolean function of four inputs. The cell's small size leads to arrays with large numbers of cells, greatly multiplying the functionality in each cell. A simple, high-speed busing network provides fast, efficient communication over medium and long distances.

The Symmetrical Array

At the heart of the Atmel architecture is a symmetrical array of identical cells, see Figure 1. The array is continuous from one edge to the other, except for bus repeaters spaced every four cells, see Figure 2 on page 5. At the intersection of each repeater row and column there is a 32 x 4 RAM block accessible by adjacent buses. The RAM can be configured as either a single-ported or dual-ported RAM(1), with either synchronous or asynchronous operation.

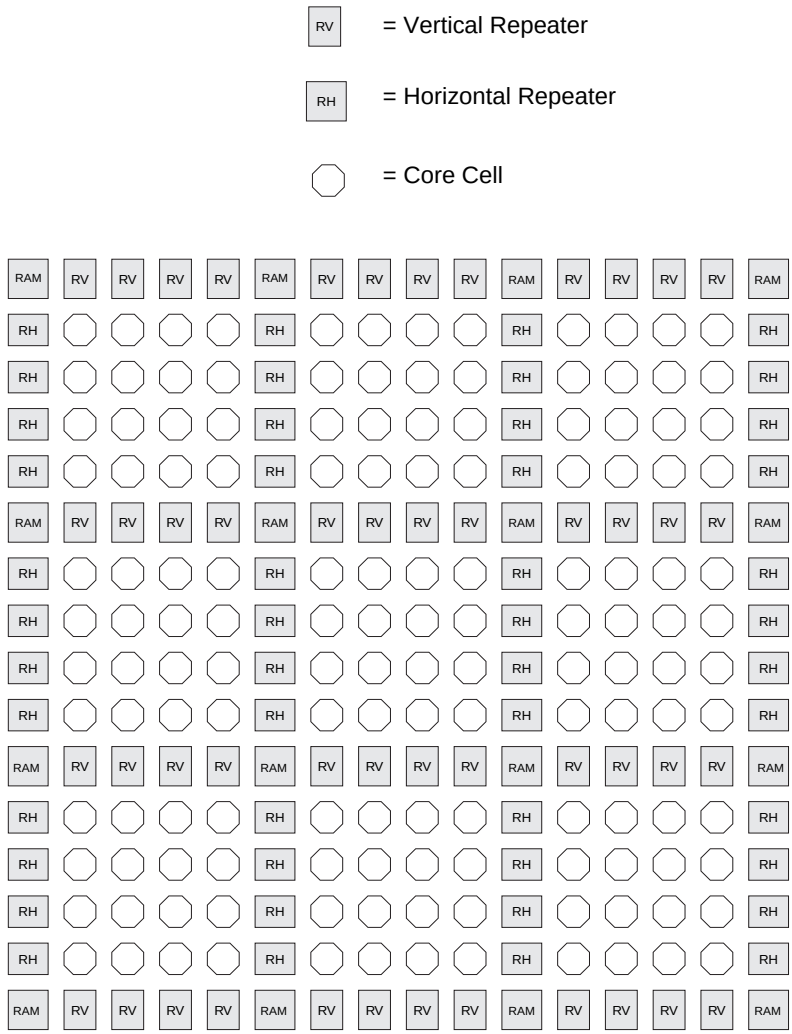
Note: 1. The right-most column can only be used as single-port RAM.

Figure 1. Symmetrical Array Surrounded by I/O (AT40K20AL)(1)



Note: 1. AT40KAL has registered I/Os. Group enable on every sector for tri-states on obufe's.

Figure 2. Floor Plan (Representative Portion)[1]



Note: 1. Repeaters regenerate signals and can connect any bus to any other bus (all pathways are legal) on the same plane. Each repeater has connections to two adjacent local-bus segments and two express-bus segments. This is done automatically using the integrated development system (IDS) tool.

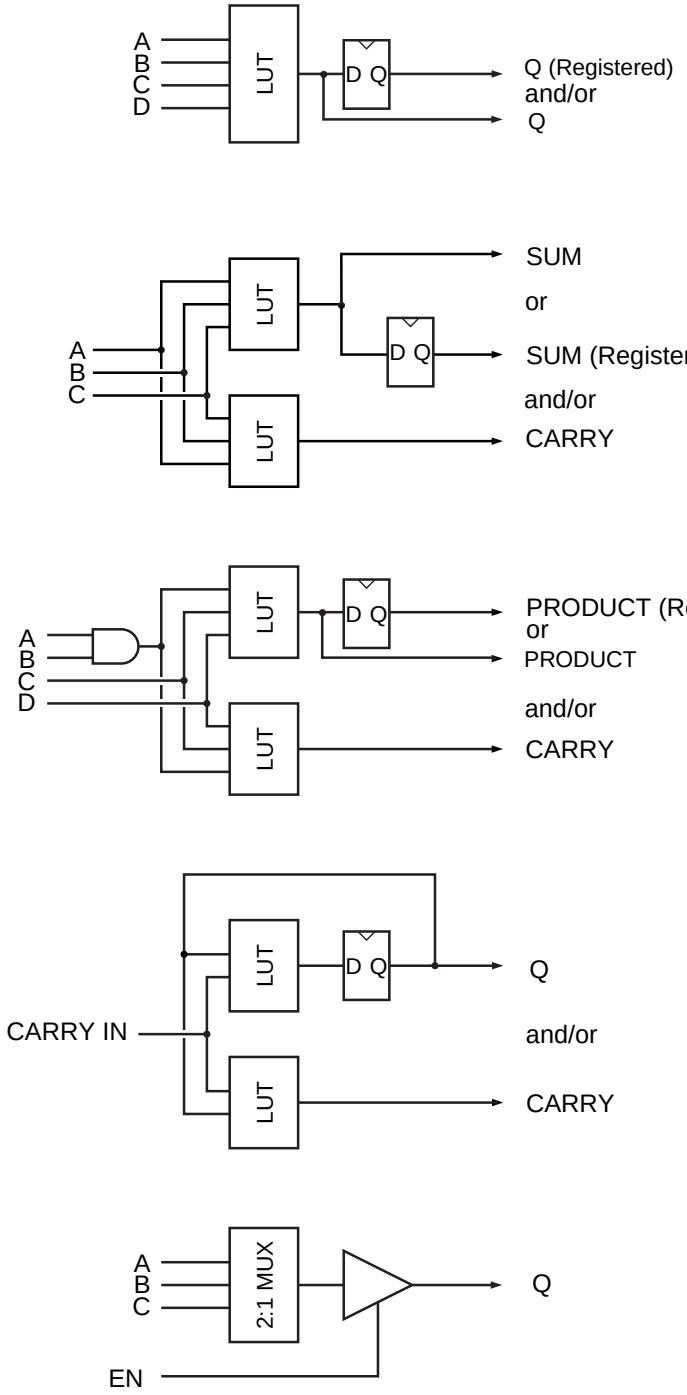
FB = Internal Feedback

Figure 6. Some Single Cell Modes



Synthesis Mode. This mode is particularly important for the use of VHDL/Verilog design. VHDL/Verilog Synthesis tools generally will produce as their output large amounts of random logic functions. Having a 4-input LUT structure gives efficient random logic optimization without the delays associated with larger LUT structures. The output of any cell may be registered, tri-stated and/or fed back into a core cell.

Arithmetic Mode is frequently used in many designs. As can be seen in the figure, the AT40KAL core cell can implement a 1-bit full adder (2-input adder with both Carry In and Carry Out) in one core cell. Note that the sum output in this diagram is registered. This output could then be tri-stated and/or fed back into the cell.

DSP/Multiplier Mode. This mode is used to efficiently implement array multipliers. An array multiplier is an array of bitwise multipliers, each implemented as a full adder with an upstream AND gate. Using this AND gate and the diagonal interconnects between cells, the array multiplier structure fits very well into the AT40KAL architecture.

Counter Mode. Counters are fundamental to almost all digital designs. They are the basis of state machines, timing chains and clock dividers. A counter is essentially an increment by one function (i.e., an adder), with the input being an output (or a decode of an output) from the previous stage. A 1-bit counter can be implemented in one core cell. Again, the output can be registered, tri-stated and/or fed back.

Tri-state/Mux Mode. This mode is used in many telecommunications applications, where data needs to be routed through more than one possible path. The output of the core cell is very often tri-statable for many inputs to many outputs data switching.

I/O Structure

The AT40KAL has registered I/Os and group enable every sector for tri-states on obuf's.

PAD

The I/O pad is the one that connects the I/O to the outside world. Note that not all I/Os have pads: the ones without pads are called Unbonded I/Os. The number of unbonded I/Os varies with the device size and package. These unbonded I/Os are used to perform a variety of bus turns at the edge of the array.

PULL-UP/PULL-DOWN

Each pad has a programmable pull-up and pull-down attached to it. This supplies a weak "1" or "0" level to the pad pin. When all other drivers are off, this control will dictate the signal level of the pad pin.

The input stage of each I/O cell has a number of parameters that can be programmed either as properties in schematic entry or in the I/O Pad Attributes editor in IDS.

CMOS

The threshold level is a CMOS-compatible level.

SCHMITT

A Schmitt trigger circuit can be enabled on the inputs. The Schmitt trigger is a regenerative comparator circuit that adds 1V hysteresis to the input. This effectively improves the rise and fall times (leading and trailing edges) of the incoming signal and can be useful for filtering out noise.

DELAYS

The input buffer can be programmed to include four different intrinsic delays as specified in the AC timing characteristics. This feature is useful for meeting data hold requirements for the input signal.

DRIVE

The output drive capabilities of each I/O are programmable. They can be set to FAST, MEDIUM or SLOW (using IDS tool). The FAST setting has the highest drive capability (20 mA at 5V) buffer and the fastest slew rate. MEDIUM produces a medium drive (14 mA at 5V) buffer, while SLOW yields a standard (6 mA at 5V) buffer.

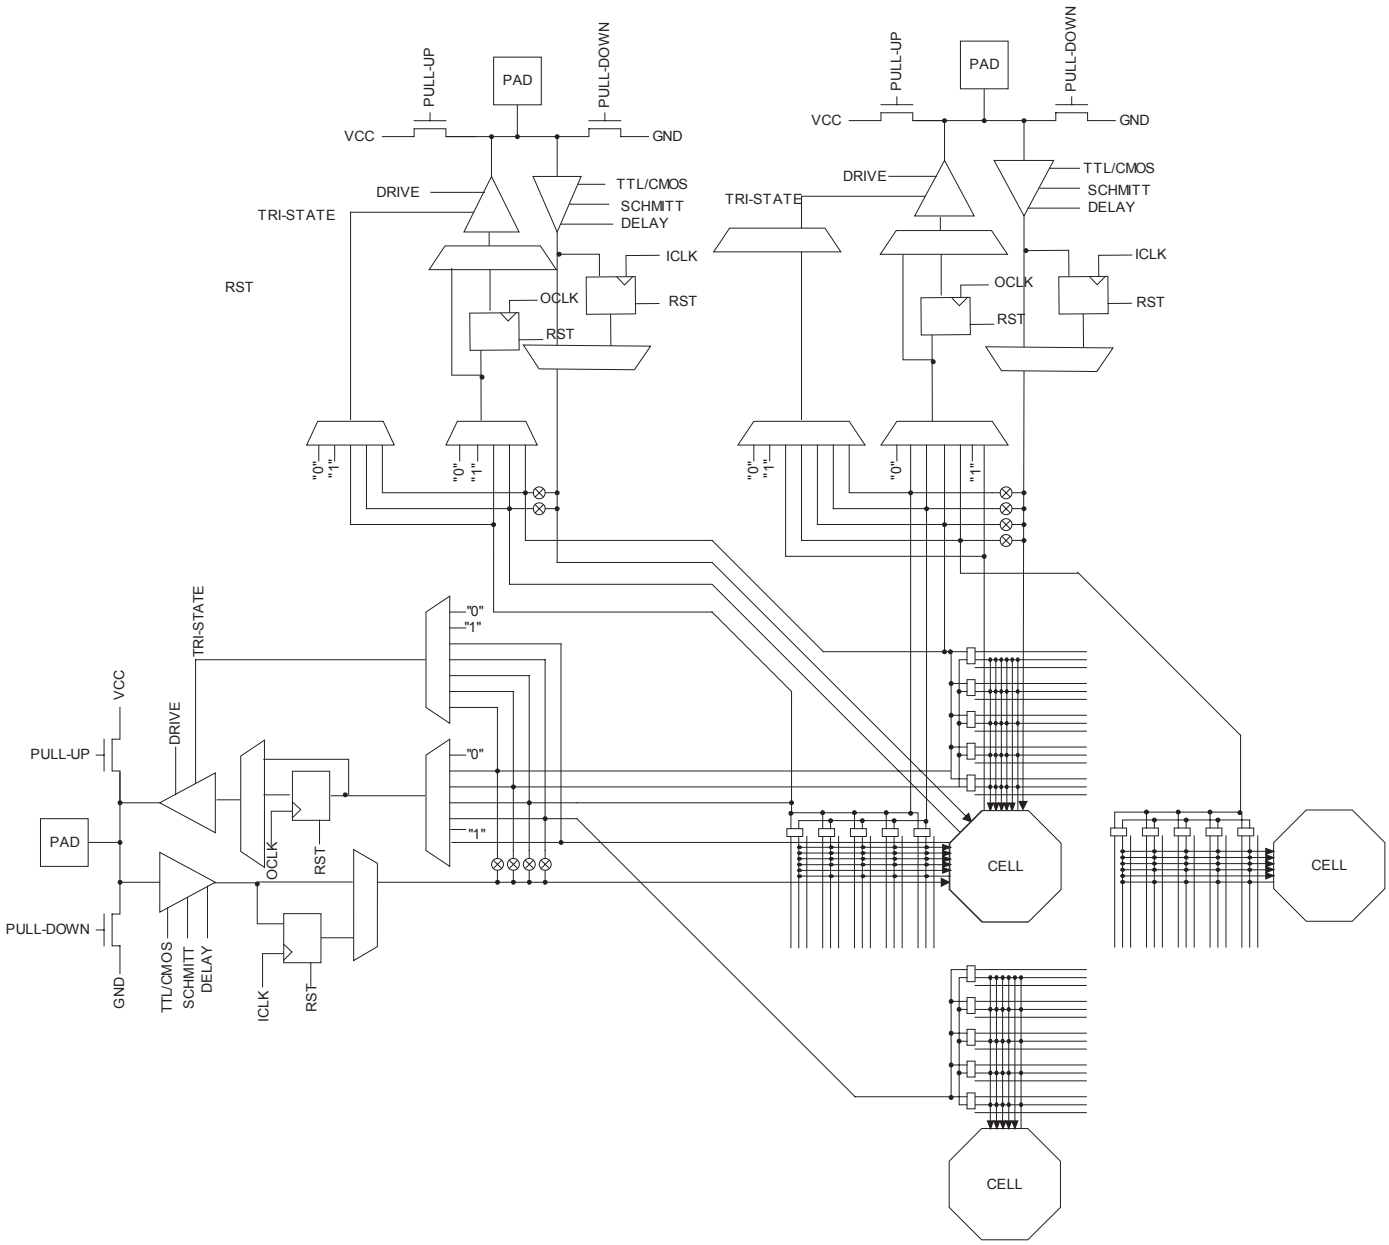
TRI-STATE

The output of each I/O can be made tri-state (0, 1 or Z), open source (1 or Z) or open drain (0 or Z) by programming an I/O's Source Selection mux. Of course, the output can be normal (0 or 1), as well.

SOURCE SELECTION MUX

The Source Selection mux selects the source for the output signal of an I/O.

Figure 14. Northwest Corner I/O (Similar NE/SE/SW Corners)



Power-On Power Supply Requirements

Atmel FPGAs require a minimum rated power supply current capacity to insure proper initialization, and the power supply ramp-up time does affect the current required. A fast ramp-up time requires more current than a slow ramp-up time.

Table 3. Power-On Power Supply Requirements[1]

Device	Description	Maximum Current[2][3]
AT40K05AL AT40K10AL	Maximum Current Supply	50 mA
AT40K20AL AT40K40AL	Maximum Current Supply	100 mA

Notes:
1. This specification applies to Commercial and Industrial grade products only.
2. Devices are guaranteed to initialize properly at 50% of the minimum current listed above. A larger capacity power supply may result in a larger initialization current.
3. Ramp-up time is measured from 0 V DC to 3.6 V DC. Peak current required lasts less than 2 ms, and occurs near the internal power on reset threshold voltage.
