Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

| Details	
Product Status	Active
Core Processor	Z8
Core Size	8-Bit
Speed	12MHz
Connectivity	-
Peripherals	POR, WDT
Number of I/O	14
Program Memory Size	1KB (1K x 8)
Program Memory Type	OTP
EEPROM Size	-
RAM Size	125 x 8
Voltage - Supply (Vcc/Vdd)	4.5V ~ 5.5V
Data Converters	-
Oscillator Type	Internal
Operating Temperature	-40°C ~ 105°C (TA)
Mounting Type	Surface Mount
Package / Case	20-SSOP (0.209", 5.30mm Width)
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z86e0412heg1866

			5.5V	10		10		ms	1

Notes:
1. Timing Reference uses 0.7 V_{CC} for a logic 1 and 0.2 V_{CC} for a logic 0.
2. Interrupt request through Port 3 (P33–P31).

Port 2, P27–P20. Port 2 is an 8-bit, bit programmable, bi-directional, Schmitt-triggered CMOS-compatible I/O port. These eight I/O lines can be configured under software control to be inputs or outputs, independently. Bits programmed as outputs can be globally programmed as either push-pull or open-drain (Figure 8).

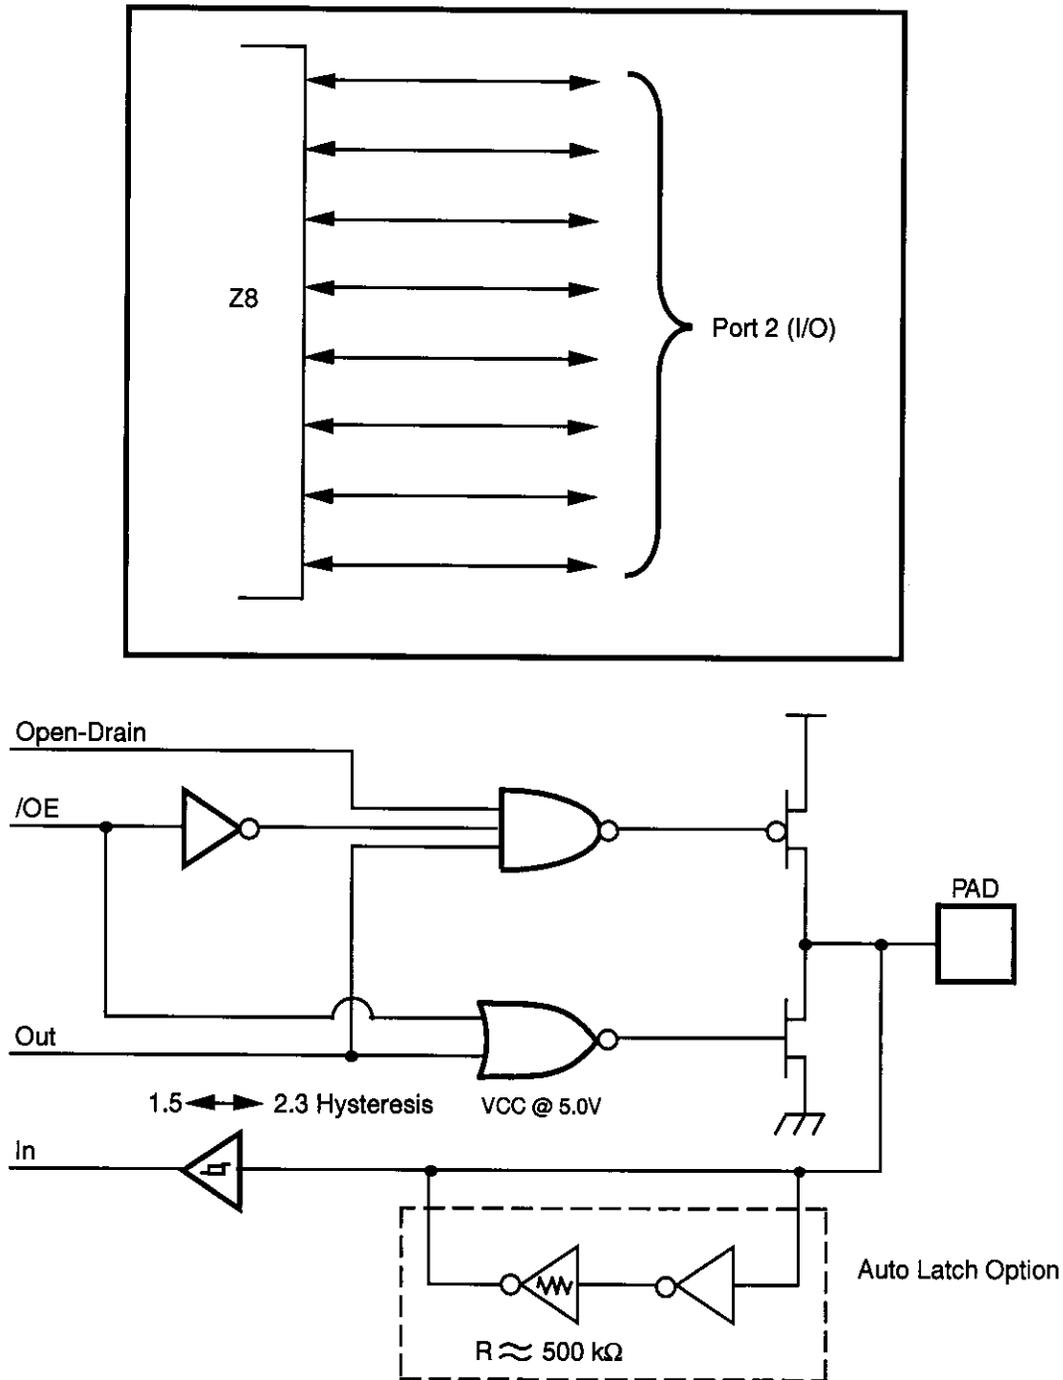

Figure 8. Port 2 Configuration

PIN FUNCTIONS (Continued)

Port 3, P33–P31. Port 3 is a 3-bit, CMOS-compatible port with three fixed input (P33–P31) lines. These three input lines can be configured under software control as digital Schmitt-trigger inputs or analog inputs.

These three input lines are also used as the interrupt sources IRQ0–IRQ3, and as the timer input signal T_{IN} (Figure 9).
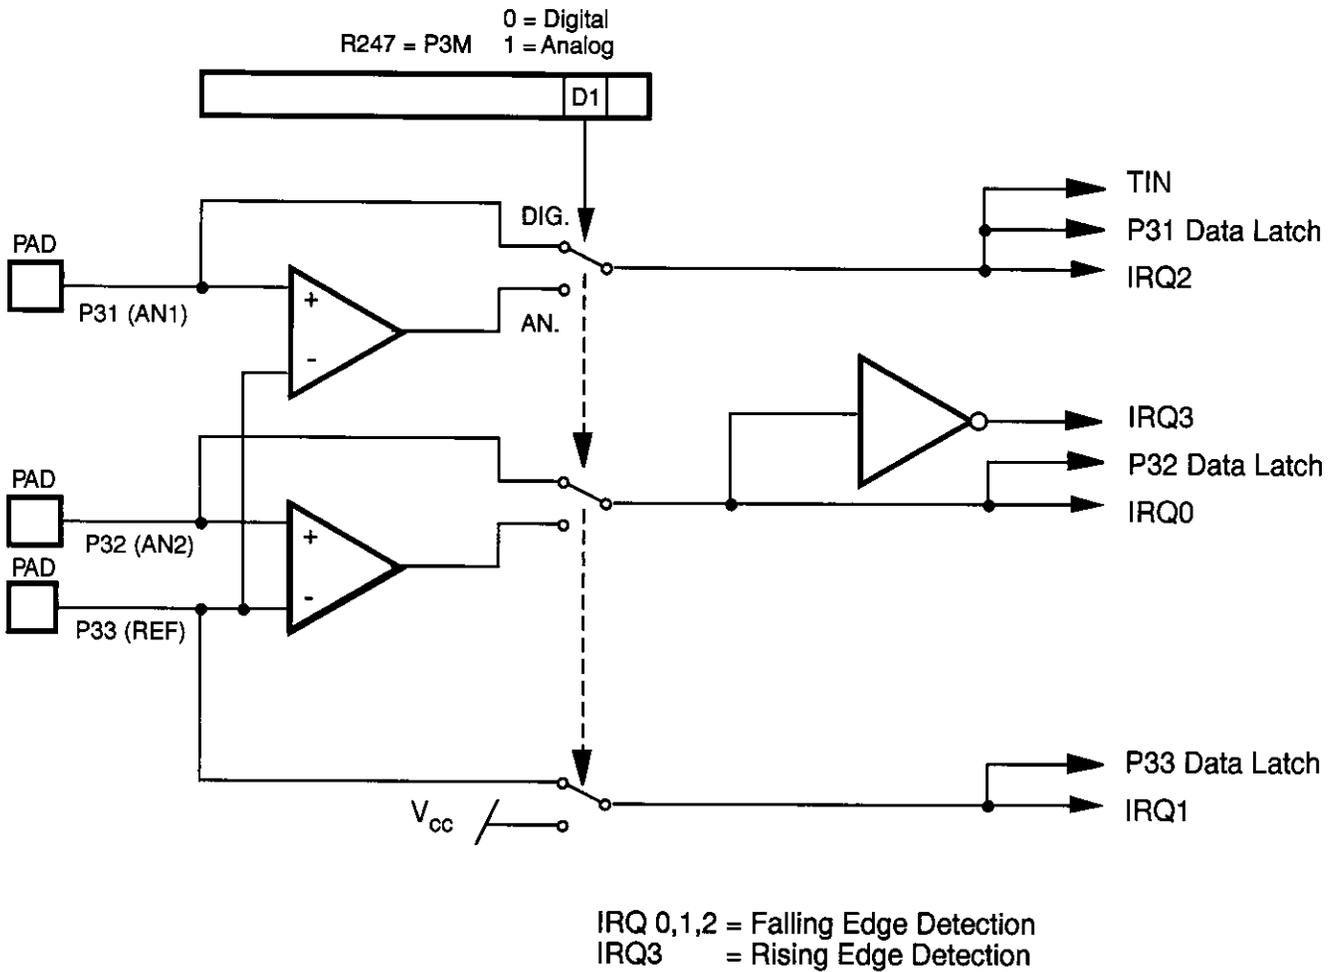

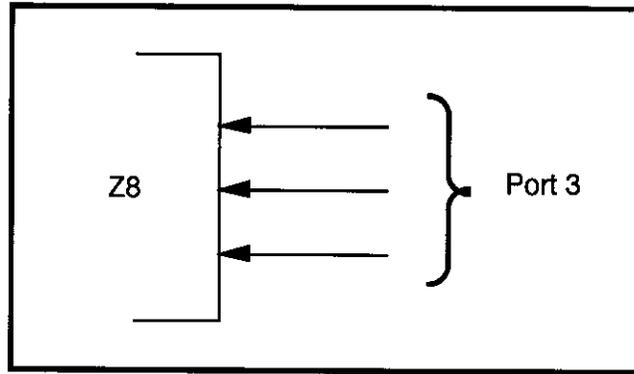

Figure 9. Port 3 Configuration

PRELIMINARY

Comparator Inputs. Two analog comparators are added to input of Port 3, P31, and P32, for interface flexibility. The comparators reference voltage P33 (REF) is common to both comparators.

Typical applications for the on-board comparators; Zero crossing detection, A/D conversion, voltage scaling, and threshold detection. In Analog Mode, P33 input functions serve as a reference voltage to the comparators.

The dual comparator (common inverting terminal) features a single power supply which discontinues power in STOP

Mode. The common voltage range is 0–4 V when the V_{CC} is 5.0V; the power supply and common mode rejection ratios are 90 dB and 60 dB, respectively.

Interrupts are generated on either edge of Comparator 2's output, or on the falling edge of Comparator 1's output. The comparator output is used for interrupt generation, Port 3 data inputs, or T_{IN} through P31. Alternatively, the comparators can be disabled, freeing the reference input (P33) for use as IRQ1 and/or P33 input.

FUNCTIONAL DESCRIPTION

The following special functions have been incorporated into the Z8 devices to enhance the standard Z8 core architecture to provide the user with increased design flexibility.

RESET. This function is accomplished by means of a Power-On Reset or a Watch-Dog Timer Reset. Upon power-up, the Power-On Reset circuit waits for T_{POR} ms, plus 18 clock cycles, then starts program execution at address 000C (Hex) (Figure 10). The Z8 control registers' reset value is shown in Table 3.

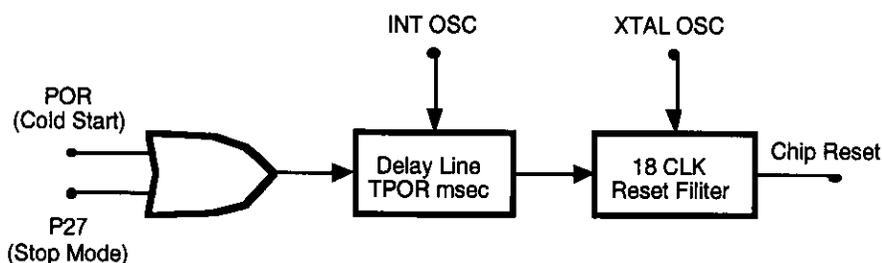

Figure 10. Internal Reset Configuration

Power-On Reset (POR). A timer circuit clocked by a dedicated on-board RC oscillator is used for a POR timer function. The POR time allows V_{CC} and the oscillator circuit to stabilize before instruction execution begins. The POR timer circuit is a one-shot timer triggered by one of the four following conditions:

■ Power-bad to power-good status

■ Stop-Mode Recovery

■ WDT time-out

■ WDH time-out

Watch-Dog Timer Reset. The WDT is a retriggerable one-shot timer that resets the Z8 if it reaches its terminal count. The WDT is initially enabled by executing the WDT instruction and is retriggered on subsequent execution of the WDT instruction. The timer circuit is driven by an on-board RC oscillator.

FUNCTIONAL DESCRIPTION (Continued)

Table 3. Control Registers

Addr.	Reg.	Reset Condition								Comments
		D7	D6	D5	D4	D3	D2	D1	D0	
FF	SPL	0	0	0	0	0	0	0	0	
FD	RP	0	0	0	0	0	0	0	0

FB	IMR	0	U	U	U	U	U	U	U	
FA	IRQ	U	U	0	0	0	0	0	0	IRQ3 is used for positive edge detection
F9	IPR	U	U	U	U	U	U	U	U	
F8*	P01M	U	U	U	0	U	U	0	1	
F7*	P3M	U	U	U	U	U	U	0	0	
F6*	P2M	1	1	1	1	1	1	1	1	Inputs after reset
F5	PRE0	U	U	U	U	U	U	U	0	
F4	T0	U	U	U	U	U	U	U	U	
F3	PRE1	U	U	U	U	U	U	0	0	
F2	T1	U	U	U	U	U	U	U	U	
F1	TMR	0	0	0	0	0	0	0	0	

Note: *Registers are not reset after a STOP-Mode Recovery using P27 pin. A subsequent reset will cause these control registers to be reconfigured as shown in Table 4 and the user must avoid bus contention on the port pins or it may affect device reliability.

Program Memory. The Z86E04/E08 addresses up to 1K/2KB of Internal Program Memory (Figure 11). The first 12 bytes of program memory are reserved for the interrupt vectors. These locations contain six 16-bit vectors that correspond to the six available interrupts. Bytes 0–1024/2048 are on-chip one-time programmable ROM.

Register File. The Register File consists of three I/O port registers, 124 general-purpose registers, and 14 control and status registers R0–R3, R4–R127 and R241–R255, respectively (Figure 12). General-purpose registers occupy the 04H to 7FH address space. I/O ports are mapped as per the existing CMOS Z8.

Figure 12. Register File

FUNCTIONAL DESCRIPTION (Continued)

Interrupts. The Z8 has six interrupts from six different sources. These interrupts are maskable and prioritized (Figure 15). The sources are divided as follows: the falling edge of P31 (AN1), P32 (AN2), P33 (REF), the rising edge of P32 (AN2), and two counter/timers. The Interrupt Mask Register globally or individually enables or disables the six interrupt requests (Table 4).

When more than one interrupt is pending, priorities are resolved by a programmable priority encoder that is controlled by the Interrupt Priority register. All Z8 interrupts are vectored through locations in program memory. When an Interrupt machine cycle is activated, an Interrupt Request is granted. This disables all subsequent interrupts, saves the Program Counter and Status Flags, and then branches to the program memory vector location reserved for that interrupt. This memory location and the next byte contain the 16-bit starting address of the interrupt service routine for that particular interrupt request.

To accommodate polled interrupt systems, interrupt inputs are masked and the interrupt request register is polled to determine which of the interrupt requests needs service.

Note: User must select any Z86E08 mode in Zilog's C12 ICEBOX™ emulator. The rising edge interrupt is not supported on the CCP emulator (a hardware/software workaround must be employed).

Table 4. Interrupt Types, Sources, and Vectors

Name	Source	Vector Location	Comments
IRQ0	AN2(P32)	0,1	External (F)Edge
IRQ1	REF(P33)	2,3	External (F)Edge
IRQ2	AN1(P31)	4,5	External (F)Edge
IRQ3	AN2(P32)	6,7	External (R)Edge
IRQ4	T0	8,9	Internal
IRQ5	T1	10,11	Internal

Notes:
F = Falling edge triggered
R = Rising edge triggered
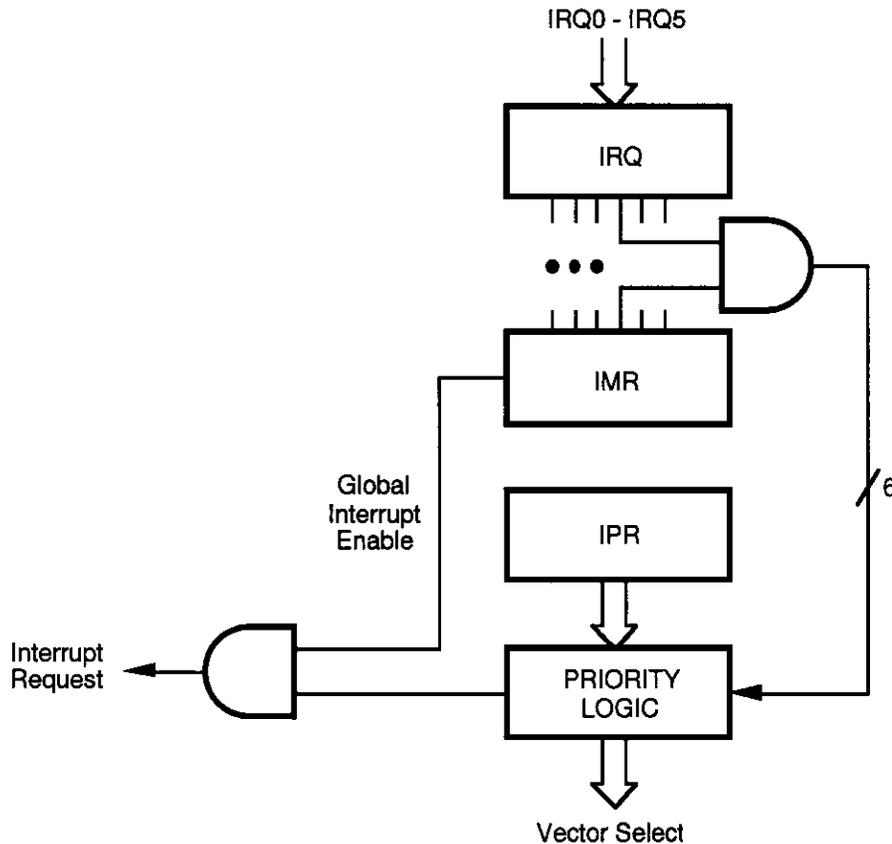

Figure 15. Interrupt Block Diagram

HALT Mode. This instruction turns off the internal CPU clock but not the crystal oscillation. The counter/timers and external interrupts IRQ0, IRQ1, IRQ2 and IRQ3 remain active. The device is recovered by interrupts, either externally or internally generated. An interrupt request must be executed (enabled) to exit HALT Mode. After the interrupt service routine, the program continues from the instruction after the HALT.

Note: On the C12 ICEBOX, the IRQ3 does not wake the device out of HALT Mode.

STOP Mode. This instruction turns off the internal clock and external crystal oscillation and reduces the standby current to 10 µA. The STOP Mode is released by a RESET through a Stop-Mode Recovery (pin P27). A Low input condition on P27 releases the STOP Mode. Program execution begins at location 000C(Hex). However, when P27 is used to release the STOP Mode, the I/O port Mode registers are not reconfigured to their default power-on conditions. This prevents any I/O, configured as output when the STOP instruction was executed, from glitching to an unknown state. To use the P27 release approach with STOP Mode, use the following instruction:

```
LD              P2M, #1XXX XXXXB
NOP
STOP
```

X = Dependent on user's application.

Note: A low level detected on P27 pin will take the device out of STOP Mode even if configured as an output.

In order to enter STOP or HALT Mode, it is necessary to first flush the instruction pipeline to avoid suspending execution in mid-instruction. To do this, the user executes a NOP (opcode=FFH) immediately before the appropriate SLEEP instruction, such as:

```
FF        NOP        ; clear the pipeline
6F        STOP       ; enter STOP Mode
                or
FF        NOP        ; clear the pipeline
7F        HALT       ; enter HALT Mode
```

Watch-Dog Timer (WDT). The Watch-Dog Timer is enabled by instruction WDT. When the WDT is enabled, it cannot be stopped by the instruction. With the WDT instruction, the WDT is refreshed when it is enabled within every 1 Twdt period; otherwise, the controller resets itself, The WDT instruction affects the flags accordingly; Z=1, S=0, V=0.

WDT = 5F (Hex)

Opcode WDT (5FH). The first time Opcode 5FH is executed, the WDT is enabled and subsequent execution clears the WDT counter. This must be done at least every T_{WDT}; otherwise, the WDT times out and generates a reset. The generated reset is the same as a power-on reset of T_{POR}, plus 18 XTAL clock cycles. The software enabled WDT does not run in STOP Mode.

Opcode WDH (4FH). When this instruction is executed it enables the WDT during HALT. If not, the WDT stops when entering HALT. This instruction does not clear the counters, it just makes it possible to have the WDT running during HALT Mode. A WDH instruction executed without executing WDT (5FH) has no effect.

Permanent WDT. Selecting the hardware enabled Permanent WDT option, will automatically enable the WDT upon exiting reset. The permanent WDT will always run in HALT Mode and STOP Mode, and it cannot be disabled.

Auto Reset Voltage (V_{LV}). The Z8 has an auto-reset built-in. The auto-reset circuit resets the Z8 when it detects the V_{CC} below V_{LV}.

Figure 17 shows the Auto Reset Voltage versus temperature. If the V_{CC} drops below the VCC operating voltage range, the Z8 will function down to the V_{LV} unless the internal clock frequency is higher than the specified maximum V_{LV} frequency.

FUNCTIONAL DESCRIPTION (Continued)

FUNCTIONAL DESCRIPTION (Continued)

Internal Address Counter. The address of Z8 is generated internally with a counter clocked through pin P01 (Clock). Each clock signal increases the address by one and the "high" level of pin P00 (Clear) will reset the address to zero. Figure 18 shows the setup time of the serial address input.

Programming Waveform. Figures 19, 20, 21 and 22 show the programming waveforms of each mode. Table 8 shows the timing of programming waveforms.

Programming Algorithm. Figure 23 shows the flow chart of the Z8 programming algorithm.

Pre-Characterization Product:

The product represented by this CPS is newly introduced and Zilog has not completed the full characterization of the product. The CPS states what Zilog knows about this product at this time, but additional features or nonconformance with some aspects of the CPS may be found, either by Zilog or its customers in the course of further application and characterization work. In addition, Zilog cautions that delivery may be uncertain at times, due to start-up yield issues.
