

Welcome to **E-XFL.COM** 

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded - Microcontrollers</u>"

Dataila	
Details	
Product Status	Active
Core Processor	PIC
Core Size	8-Bit
Speed	48MHz
Connectivity	I <sup>2</sup> C, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, HLVD, POR, PWM, WDT
Number of I/O	24
Program Memory Size	8KB (4K x 16)
Program Memory Type	FLASH
EEPROM Size	256 x 8
RAM Size	512 x 8
Voltage - Supply (Vcc/Vdd)	1.8V ~ 3.6V
Data Converters	A/D 11x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 125°C (TA)
Mounting Type	Surface Mount
Package / Case	28-SOIC (0.295", 7.50mm Width)
Supplier Device Package	28-SOIC
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic18f23k20-e-so

In addition to the code memory space, there are three blocks in the configuration and ID space that are accessible to the user through table reads and table writes. Their locations in the memory map are shown in Figure 2-10.

Users may store identification information (ID) in eight ID registers. These ID registers are mapped in addresses 200000h through 200007h. The ID locations read out normally, even after code protection is applied.

Locations 300000h through 30000Dh are reserved for the Configuration bits. These bits select various device options and are described in **Section 5.0 "Configuration Word"**. These Configuration bits read out normally, even after code protection.

Locations 3FFFFEh and 3FFFFFh are reserved for the device ID bits. These bits may be used by the programmer to identify what device type is being programmed and are described in **Section 5.0 "Configuration Word"**. These device ID bits read out normally, even after code protection.

#### 2.3.1 MEMORY ADDRESS POINTER

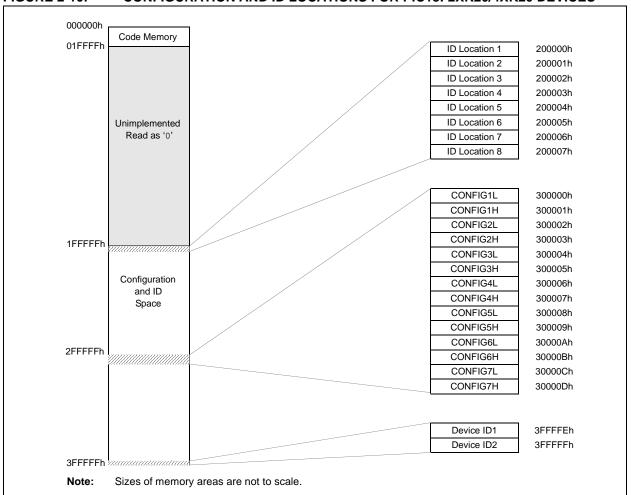

Memory in the address space, 0000000h to 3FFFFFh, is addressed via the Table Pointer register, which is comprised of three Pointer registers:

- · TBLPTRU, at RAM address 0FF8h
- · TBLPTRH, at RAM address 0FF7h
- · TBLPTRL, at RAM address 0FF6h

TBLPTRU	TBLPTRH	TBLPTRL
Addr[21:16]	Addr[15:8]	Addr[7:0]

The 4-bit command, '0000' (core instruction), is used to load the Table Pointer prior to using any read or write operations.

FIGURE 2-10: CONFIGURATION AND ID LOCATIONS FOR PIC18F2XK20/4XK20 DEVICES

# 2.6 Entering and Exiting Low-Voltage ICSP Program/Verify Mode

When the LVP Configuration bit is '1' (see **Section 5.3** "**Single-Supply ICSP Programming**"), the Low-Voltage ICSP mode is enabled. As shown in Figure 2-14, Low-Voltage ICSP Program/Verify mode is entered by holding PGC and PGD low, placing a logic high on PGM and then raising MCLR/VPP/RE3 to VIH. In this mode, the RB5/PGM pin is dedicated to the programming function and ceases to be a general purpose I/O pin. Figure 2-15 shows the exit sequence.

The sequence that enters the device into the Program/ Verify mode places all unused I/Os in the high-impedance state.

FIGURE 2-14: ENTERING LOW-VOLTAGE PROGRAM/VERIFY MODE

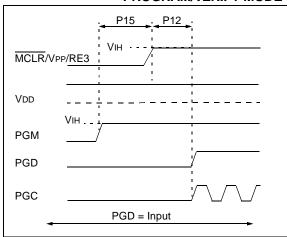

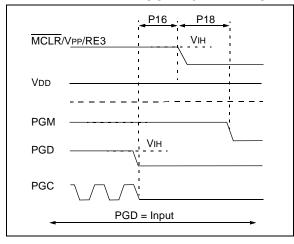

FIGURE 2-15: EXITING LOW-VOLTAGE PROGRAM/VERIFY MODE

## 2.7 Serial Program/Verify Operation

The PGC pin is used as a clock input pin and the PGD pin is used for entering command bits and data input/output during serial operation. Commands and data are transmitted on the rising edge of PGC, latched on the falling edge of PGC and are Least Significant bit (LSb) first.

#### 2.7.1 4-BIT COMMANDS

All instructions are 20 bits, consisting of a leading 4-bit command followed by a 16-bit operand, which depends on the type of command being executed. To input a command, PGC is cycled four times. The commands needed for programming and verification are shown in Table 2-6.

Depending on the 4-bit command, the 16-bit operand represents 16 bits of input data or 8 bits of input data and 8 bits of output data.

Throughout this specification, commands and data are presented as illustrated in Table 2-7. The 4-bit command is shown Most Significant bit (MSb) first. The command operand, or "Data Payload", is shown <MSB><LSB>. Figure 2-16 demonstrates how to serially present a 20-bit command/operand to the device.

#### 2.7.2 CORE INSTRUCTION

The core instruction passes a 16-bit instruction to the CPU core for execution. This is needed to set up registers as appropriate for use with other commands.

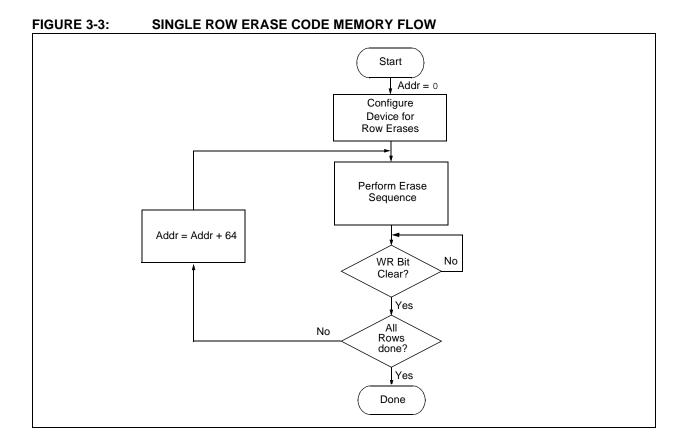

TABLE 2-6: COMMANDS FOR PROGRAMMING

Description	4-Bit Command
Core Instruction (Shift in16-bit instruction)	0000

Note 1: See Figure 4-4 for details on shift out data timing.

# 3.2 Code Memory Programming

Programming code memory is accomplished by first loading data into the write buffer and then initiating a programming sequence. The write and erase buffer sizes shown in Table 3-4 can be mapped to any location of the same size beginning at 000000h. The actual memory write sequence takes the contents of this buffer and programs the proper amount of code memory that contains the Table Pointer.

The programming duration is externally timed and is controlled by PGC. After a Start Programming command is issued (4-bit command, '1111'), a  $\mathtt{NOP}$  is issued, where the 4th PGC is held high for the duration of the programming time, P9.

After PGC is brought low, the programming sequence is terminated. PGC must be held low for the time specified by parameter P10 to allow high-voltage discharge of the memory array.

The code sequence to program a PIC18F2XK20/4XK20 device is shown in Table 3-5. The flowchart shown in Figure 3-4 depicts the logic necessary to completely write a PIC18F2XK20/4XK20 device. The timing diagram that details the Start Programming command and parameters P9 and P10 is shown in Figure 3-5.

**Note:** The TBLPTR register must point to the same region when initiating the programming sequence as it did when the write buffers were loaded.

To continue writing data, repeat steps 2 through 4, where the Address Pointer is incremented by 2 at each iteration of the loop.				

FIGURE 3-4: PROGRAM CODE MEMORY FLOW

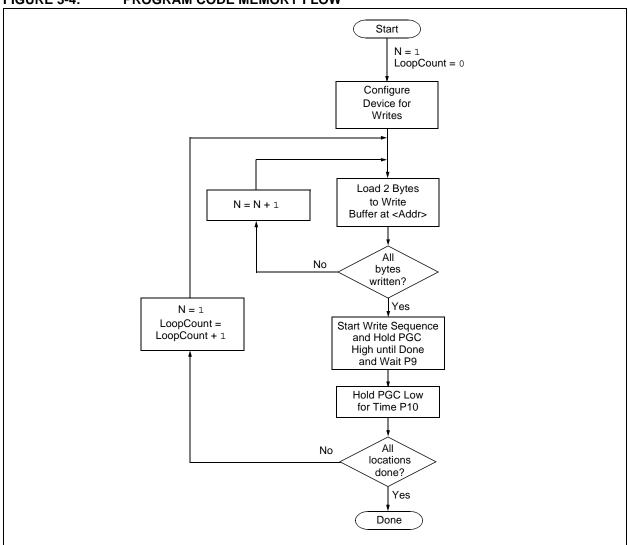

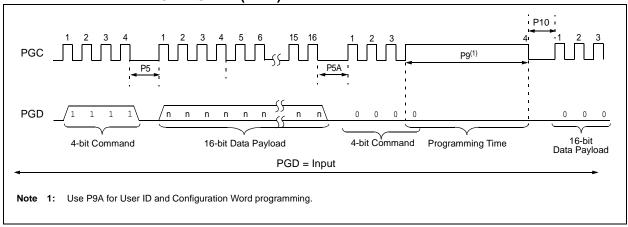

FIGURE 3-5: TABLE WRITE AND START PROGRAMMING INSTRUCTION TIMING DIAGRAM (1111)

#### 3.2.1 MODIFYING CODE MEMORY

The previous programming example assumed that the device has been Bulk Erased prior to programming (see **Section 3.1.1** "**High-Voltage ICSP Bulk Erase**"). It may be the case, however, that the user wishes to modify only a section of an already programmed device.

The appropriate number of bytes required for the erase buffer must be read out of code memory (as described in **Section 4.2 "Verify Code Memory and ID Locations"**) and buffered. Modifications can be made on this buffer. Then, the block of code memory that was read out must be erased and rewritten with the modified data.

The WREN bit must be set if the WR bit in EECON1 is used to initiate a write sequence.

To continue modifying data, repeat Steps 2 through 6, where the Address Pointer is incremented by the appropriate number of bytes (see Table 3-4) at each iteration of the loop. The write cycle must be repeated enough times to completely rewrite the contents of the erase buffer.

0.000 00				
Step 8: Disable wr	rites.			
0000	94 A6	BCF	EECON1, WREN	

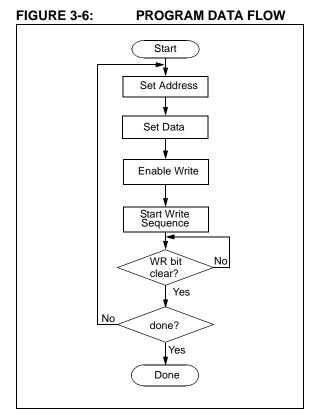

# 3.3 Data EEPROM Programming

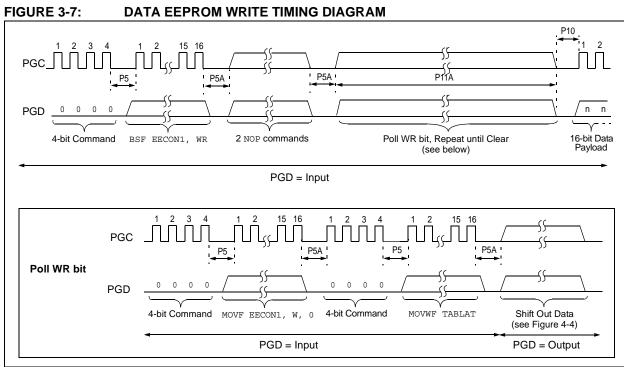

Data EEPROM is accessed one byte at a time via an Address Pointer (register pair EEADRH:EEADR) and a data latch (EEDATA). Data EEPROM is written by loading EEADRH:EEADR with the desired memory location, EEDATA with the data to be written and initiating a memory write by appropriately configuring the EECON1 register. A byte write automatically erases the location and writes the new data (erase-before-write).

When using the EECON1 register to perform a data EEPROM write, both the EEPGD and CFGS bits must be cleared (EECON1<7:6> = 00). The WREN bit must be set (EECON1<2> = 1) to enable writes of any sort and this must be done prior to initiating a write sequence. The write sequence is initiated by setting the WR bit (EECON1<1> = 1).

The write begins on the falling edge of the 24th PGC after the WR bit is set. It ends when the WR bit is cleared by hardware.

After the programming sequence terminates, PGC must be held low for the time specified by parameter P10 to allow high-voltage discharge of the memory array.

## 3.5 Boot Block Programming

The code sequence detailed in Table 3-5 should be used, except that the address used in "Step 2" will be in the range of 000000h to 0007FFh.

# 3.6 Configuration Bits Programming

Unlike code memory, the Configuration bits are programmed a byte at a time. The Table Write, Begin Programming 4-bit command ('1111') is used, but only 8 bits of the following 16-bit payload will be written. The LSB of the payload will be written to even addresses and the MSB will be written to odd addresses. The code sequence to program two consecutive configuration locations is shown in Table 3-9. See Figure 3-5 for the timing diagram.

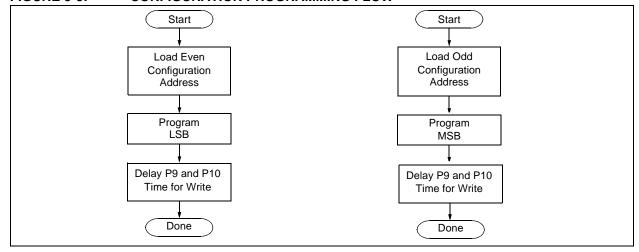

**Note:** The address must be explicitly written for each byte programmed. The addresses can not be incremented in this mode.

TABLE 3-9: SET ADDRESS POINTER TO CONFIGURATION LOCATION

IADLE 3-3.	SET ADDRESS FORMER TO CONFIGURATION LOCATION		
4-bit Command	Data Payload	Core Instruction	
Step 1: Direct a	ccess to config memory.

0000	0E 00	MOVLW 00h	
0000	6E F7	MOVWF TBLPRTH	
0000	0E 00	MOVLW 00h	
0000	6E F6	MOVWF TBLPTRL	
1111	<msb ignored=""><lsb></lsb></msb>	Load 2 bytes and start programming.	
0000	00 00	NOP - hold PGC high for time P9 and low for time P10.	
0000	0E 01	MOVLW 01h	
0000	6E F6	MOVWF TBLPTRL	
1111	<msb><lsb ignored=""></lsb></msb>	Load 2 bytes and start programming.	
0000	00 00	NOP - hold PGC high for time P9A and low for time P10.	

Note 1: Enabling the write protection of Configuration bits (WRTC = 0 in CONFIG6H) will prevent further writing of Configuration bits. Always write all the Configuration bits before enabling the write protection for Configuration bits.

FIGURE 3-8: CONFIGURATION PROGRAMMING FLOW

#### 4.0 READING THE DEVICE

# 4.1 Read Code Memory, ID Locations and Configuration Bits

Code memory is accessed one byte at a time via the 4-bit command, '1001' (table read, post-increment). The contents of memory pointed to by the Table Pointer (TBLPTRU:TBLPTRH:TBLPTRL) are serially output on PGD.

The 4-bit command is shifted in LSb first. The read is executed during the next 8 clocks, then shifted out on PGD during the last 8 clocks, LSb to MSb. A delay of P6 must be introduced after the falling edge of the 8th

PGC of the operand to allow PGD to transition from an input to an output. During this time, PGC must be held low (see Figure 4-1). This operation also increments the Table Pointer by one, pointing to the next byte in code memory for the next read.

This technique will work to read any memory in the 000000h to 3FFFFFh address space, so it also applies to the reading of the ID and Configuration registers.

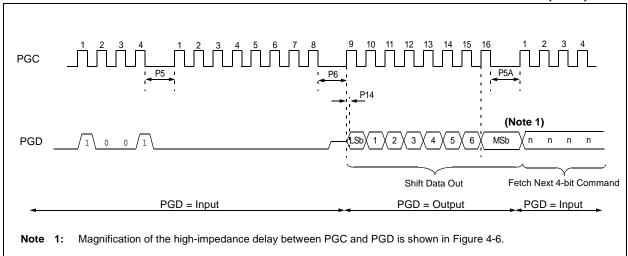

When table read protection is enabled, the first read access to a protected block should be discarded and the read repeated to retrieve valid data. Subsequent reads of the same block can be performed normally.

TABLE 4-1: READ CODE MEMORY SEQUENCE

4-bit Command	Data Payload	Core Instruction	
Step 1: Set Tabl	e Pointer		
0000	0E <addr[21:16]></addr[21:16]>	MOVLW Addr[21:16]

0000	6E F6	MOVWF TBLPTRL	
Step 2: Read memory and then shift out on PGD, LSb to MSb			
1001	00 00	TBLRD *+	

Note:

# FIGURE 4-1: TABLE READ POST-INCREMENT INSTRUCTION TIMING DIAGRAM (1001)

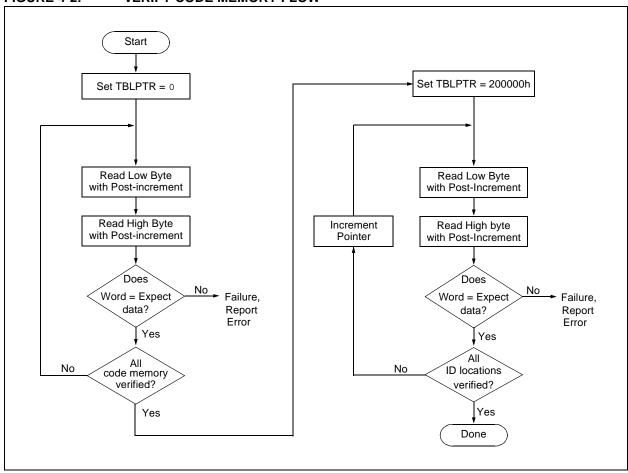

# 4.2 Verify Code Memory and ID Locations

The verify step involves reading back the code memory space and comparing it against the copy held in the programmer's buffer. Memory reads occur a single byte at a time, so two bytes must be read to compare against the word in the programmer's buffer. Refer to Section 4.1 "Read Code Memory, ID Locations and Configuration Bits" for implementation details of reading code memory.

The Table Pointer must be manually set to 200000h (base address of the ID locations) once the code memory has been verified. The post-increment feature of the table read 4-bit command can not be used to increment the Table Pointer beyond the code memory space. In a 64-Kbyte device, for example, a post-increment read of address FFFFh will wrap the Table Pointer back to 000000h, rather than point to unimplemented address 010000h.

FIGURE 4-2: VERIFY CODE MEMORY FLOW

## 4.3 Verify Configuration Bits

A configuration address may be read and output on PGD via the 4-bit command, '1001'. Configuration data is read and written in a byte-wise fashion, so it is not necessary to merge two bytes into a word prior to a compare. The result may then be immediately compared to the appropriate configuration data in the programmer's memory for verification. Refer to Section 4.1 "Read Code Memory, ID Locations and Configuration Bits" for implementation details of reading configuration data.

## 4.4 Read Data EEPROM Memory

Data EEPROM is accessed one byte at a time via an Address Pointer (register pair EEADRH:EEADR) and a data latch (EEDATA). Data EEPROM is read by loading EEADRH:EEADR with the desired memory location and initiating a memory read by appropriately configuring the EECON1 register. The data will be loaded into EEDATA, where it may be serially output on PGD via the 4-bit command, '0010' (Shift Out Data Holding register). A delay of P6 must be introduced after the falling edge of the 8th PGC of the operand to allow PGD to transition from an input to an output. During this time, PGC must be held low (see Figure 4-4).

The command sequence to read a single byte of data is shown in Table 4-2.

TABLE 5-4: CHECKSUM COMPUTATION (CONTINUED)

Device	Code- Protect	Checksum	Blank Value	0xAA at 0 and Max Address
	None	SUM[0000:07FF]+SUM[0800:1FFF]+SUM[2000:3FFF]+ SUM[4000:5FFF]+SUM[6000:7FFF]+(CONFIG1L & 00h)+ (CONFIG1H & CFh)+(CONFIG2L & 1Fh)+(CONFIG2H & 1F)+ (CONFIG3L & 00h)+(CONFIG3H & 8Fh)+(CONFIG4L & C5h)+ (CONFIG4H & 00h)+(CONFIG5L & 0Fh)+(CONFIG5H & C0h)+ (CONFIG6L & 0Fh)+(CONFIG6H & E0h)+(CONFIG7L & 0Fh)+ (CONFIG7H & 40h)	8362h	82B8h
PIC18FX5K20	Boot Block	SUM[0800:1FFF]+SUM[2000:3FFF]+SUM[4000:5FFF]+SUM[6000:7FFF]+SUM[0800:1FFF]+SUM[6000:7FFF]+SUM[0800:1FFF]+SUM[0800:3FFF]+SUM[4000:5FFF]+SUM[6000:7FFF]+SUM[0800:1FFF]+SUM[08	8B35h	8AEAh
	Boot/ Block 0/ Block 1	SUM[4000:5FFF]+SUM[6000:7FFF]+(CONFIG1L & 00h)+ (CONFIG1H & CFh)+(CONFIG2L & 1Fh)+(CONFIG2H & 1F)+ (CONFIG3L & 00h)+(CONFIG3H & 8Fh)+(CONFIG4L & C5h)+ (CONFIG4H & 00h)+(CONFIG5L & 0Fh)+(CONFIG5H & C0h)+ (CONFIG6L & 0Fh)+(CONFIG6H & E0h)+(CONFIG7L & 0Fh)+ (CONFIG7H & 40h)+SUM_ID	C332h	C2E7h
	All	(CONFIG1L & 00h)+(CONFIG1H & CFh)+(CONFIG2L & 1Fh)+ (CONFIG2H & 1F)+(CONFIG3L & 00h)+(CONFIG3H & 8Fh)+ (CONFIG4L & C5h)+(CONFIG4H & 00h)+(CONFIG5L & 0Fh)+ (CONFIG5H & C0h)+(CONFIG6L & 0Fh)+(CONFIG6H & E0h)+ (CONFIG7L & 0Fh)+(CONFIG7H & 40h)+SUM_ID	0326h	0330h

 Legend:
 Item
 Description

CONFIGx = Configuration Word

SUM[a:b] = Sum of locations, a to b inclusive

SUM\_ID = Byte-wise sum of lower four bits of all customer ID locations

+ = Addition & = Bit-wise AND

# 6.0 AC/DC CHARACTERISTICS TIMING REQUIREMENTS FOR PROGRAM/ VERIFY TEST MODE (CONTINUED)

**Standard Operating Conditions** 

Operating Temperature: 25°C is recommended

•						
Param No.	Sym.	Characteristic	Min.	Max.	Units	Conditions
P12	THLD2	Input Data Hold Time from MCLR/VPP/RE3↑	2	_	μS	
P13	TSET2	VDD ↑ Setup Time to MCLR/VPP/RE3 ↑	100	_	ns	
P14	TVALID	Data Out Valid from PGC ↑	10	_	ns	
P15	TSET3	PGM ↑ Setup Time to MCLR/VPP/RE3 ↑	2	_	μS	
P16	TDLY8	Delay between Last PGC $\downarrow$ and $\overline{\text{MCLR}}/\text{VPP/RE3} \downarrow$	0	_	s	
P17	THLD3	MCLR/VPP/RE3 ↓ to VDD ↓	_	100	ns	
P18	THLD4	MCLR/VPP/RE3 ↓ to PGM ↓	0	_	s	
P19	THIZ	Delay from PGC ↑ to PGD High-Z	3	10	nS	
P20	TPPDP	Hold time after VPP changes	5	_	μS	

Note 1: Do not allow excess time when transitioning MCLR between VIL and VIHH; this can cause spurious program executions to occur. The maximum transition time is:

<sup>1</sup> TCY + TPWRT (if enabled) + 1024 ToSC (for LP, HS, HS/PLL and XT modes only) + 2 ms (for HS/PLL mode only) + 1.5  $\mu$ s (for EC mode only) where TCY is the instruction cycle time, TPWRT is the Power-up Timer period and ToSC is the oscillator period. For specific values, refer to the Electrical Characteristics section of the device data sheet for the particular device.
