
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I²C, IrDA, LINbus, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, HLVD, POR, PWM, WDT
Number of I/O	38
Program Memory Size	16KB (5.5K x 24)
Program Memory Type	FLASH
EEPROM Size	512 x 8
RAM Size	2K x 8
Voltage - Supply (Vcc/Vdd)	2V ~ 5.5V
Data Converters	A/D 16x12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-VQFN Exposed Pad
Supplier Device Package	44-QFN (8x8)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fv16ka304-i-ml

4.3.3 READING DATA FROM PROGRAM MEMORY USING PROGRAM SPACE VISIBILITY

The upper 32 Kbytes of data space may optionally be mapped into a 16K word page (in PIC24FV16KA3XX devices) and a 32K word page (in PIC24FV32KA3XX devices) of the program space. This provides transparent access of stored constant data from the data space without the need to use special instructions (i.e., `TBLRDL/H`).

Program space access through the data space occurs if the MSb of the data space EA is '`1`' and PSV is enabled by setting the PSV bit in the CPU Control (CORCON<2>) register. The location of the program memory space to be mapped into the data space is determined by the Program Space Visibility Page Address (PSVPAG) register. This 8-bit register defines any one of 256 possible pages of 16K words in program space. In effect, PSVPAG functions as the upper 8 bits of the program memory address, with the 15 bits of the EA functioning as the lower bits.

By incrementing the PC by 2 for each program memory word, the lower 15 bits of data space addresses directly map to the lower 15 bits in the corresponding program space addresses.

Data reads from this area add an additional cycle to the instruction being executed, since two program memory fetches are required.

Although each data space address, 8000h and higher, maps directly into a corresponding program memory address (see Figure 4-7), only the lower 16 bits of the 24-bit program word are used to contain the data. The upper 8 bits of any program space location used as data should be programmed with '`1111 1111`' or '`0000 0000`' to force a `NOP`. This prevents possible issues should the area of code ever be accidentally executed.

Note:	PSV access is temporarily disabled during table reads/writes.

For operations that use PSV and are executed outside a `REPEAT` loop, the `MOV` and `MOV.D` instructions will require one instruction cycle in addition to the specified execution time. All other instructions will require two instruction cycles in addition to the specified execution time.

For operations that use PSV, which are executed inside a `REPEAT` loop, there will be some instances that require two instruction cycles in addition to the specified execution time of the instruction:

- Execution in the first iteration
- Execution in the last iteration
- Execution prior to exiting the loop due to an interrupt
- Execution upon re-entering the loop after an interrupt is serviced

Any other iteration of the `REPEAT` loop will allow the instruction accessing data, using PSV, to execute in a single cycle.

-n = Value at POR	'1' = Bit is set	R = Readable bit	W = Writable bit
'0' = Bit is cleared	x = Bit is unknown	U = Unimplemented bit, read as '0'	

bit 15 **WR:** Write Control bit
1 = Initiates a Flash memory program or erase operation. The operation is self-timed and the bit is cleared by hardware once the operation is complete.
0 = Program or erase operation is complete and inactive

bit 14 **WREN:** Write Enable bit
1 = Enables Flash program/erase operations
0 = Inhibits Flash program/erase operations

bit 13 **WRERR:** Write Sequence Error Flag bit
1 = An improper program or erase sequence attempt, or termination, has occurred (bit is set automatically on any set attempt of the WR bit)
0 = The program or erase operation completed normally

bit 12 **PGMONLY:** Program Only Enable bit(4)

bit 11-7 **Unimplemented:** Read as '0'

bit 6 **ERASE:** Erase/Program Enable bit
1 = Performs the erase operation specified by NVMOP<5:0> on the next WR command
0 = Performs the program operation specified by NVMOP<5:0> on the next WR command

bit 5-0 **NVMOP<5:0>:** Programming Operation Command Byte bits(1)
Erase Operations (when ERASE bit is '1'):
1010xx = Erases entire boot block (including code-protected boot block)(2)
1001xx = Erases entire memory (including boot block, configuration block, general block)(2)
011010 = Erases 4 rows of Flash memory(3)
011001 = Erases 2 rows of Flash memory(3)
011000 = Erases 1 row of Flash memory(3)
0101xx = Erases entire configuration block (except code protection bits)
0100xx = Erases entire data EEPROM(4)
0011xx = Erases entire general memory block programming operations
0001xx = Writes 1 row of Flash memory (when ERASE bit is '0')(3)

Note 1: All other combinations of NVMOP<5:0> are no operation.
2: These values are available in ICSP™ mode only. Refer to the device programming specification.
3: The address in the Table Pointer decides which rows will be erased.
4: This bit is used only while accessing data EEPROM.

bit 6-4 **IC3IP<2:0>:** Input Capture Channel 3 Event Interrupt Priority bits
111 = Interrupt is Priority 7 (highest priority interrupt)
•
•
•
001 = Interrupt is Priority 1
000 = Interrupt source is disabled

bit 3-0 **Unimplemented:** Read as ‘0’

NOTES:

The following code sequence for a clock switch is recommended:

1. Disable interrupts during the OSCCON register unlock and write sequence.
2. Execute the unlock sequence for the OSCCON high byte by writing 78h and 9Ah to OSCCON<15:8>, in two back-to-back instructions.
3. Write new oscillator source to the NOSCx bits in the instruction immediately following the unlock sequence.
4. Execute the unlock sequence for the OSCCON low byte by writing 46h and 57h to OSCCON<7:0>, in two back-to-back instructions.
5. Set the OSWEN bit in the instruction immediately following the unlock sequence.
6. Continue to execute code that is not clock-sensitive (optional).
7. Invoke an appropriate amount of software delay (cycle counting) to allow the selected oscillator and/or PLL to start and stabilize.
8. Check to see if OSWEN is '0'. If it is, the switch was successful. If OSWEN is still set, then check the LOCK bit to determine the cause of failure.

The core sequence for unlocking the OSCCON register and initiating a clock switch is shown in Example 9-1.

EXAMPLE 9-1: BASIC CODE SEQUENCE FOR CLOCK SWITCHING

```
;Place the new oscillator selection in W0
;OSCCONH (high byte) Unlock Sequence
MOV         #OSCCONH, w1
MOV         #0x78, w2
MOV         #0x9A, w3
MOV.b       w2, [w1]
MOV.b       w3, [w1]
;Set new oscillator selection
MOV.b       WREG, OSCCONH
;OSCCONL (low byte) unlock sequence
MOV         #OSCCONL, w1
MOV         #0x46, w2
MOV         #0x57, w3
MOV.b       w2, [w1]
MOV.b       w3, [w1]
;Start oscillator switch operation
BSET        OSCCON,#0
```

9.5 Reference Clock Output

In addition to the CLKO output (FOSC/2) available in certain oscillator modes, the device clock in the PIC24FV32KA304 family devices can also be configured to provide a reference clock output signal to a port pin. This feature is available in all oscillator configurations and allows the user to select a greater range of clock submultiples to drive external devices in the application.

This reference clock output is controlled by the REFOCON register (Register 9-4). Setting the ROEN bit (REFOCON<15>) makes the clock signal available on the REFO pin. The RODIVx bits (REFOCON<11:8>) enable the selection of 16 different clock divider options.

The ROSSLP and ROSEL bits (REFOCON<13:12>) control the availability of the reference output during Sleep mode. The ROSEL bit determines if the oscillator on OSC1 and OSC2, or the current system clock source, is used for the reference clock output. The ROSSLP bit determines if the reference source is available on REFO when the device is in Sleep mode.

To use the reference clock output in Sleep mode, both the ROSSLP and ROSEL bits must be set. The device clock must also be configured for one of the primary modes (EC, HS or XT); otherwise, if the ROSEL bit is not also set, the oscillator on OSC1 and OSC2 will be powered down when the device enters Sleep mode. Clearing the ROSEL bit allows the reference output frequency to change as the system clock changes during any clock switches.

NOTES:

bit 7							bit 0

Legend:	HC = Hardware Clearable bit		
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as ‘0’	
-n = Value at POR	‘1’ = Bit is set	‘0’ = Bit is cleared	x = Bit is unknown

bit 15 **I2CEN:** I2Cx Enable bit
1 = Enables the I2Cx module, and configures the SDAx and SCLx pins as serial port pins
0 = Disables the I2Cx module; all I²C™ pins are controlled by port functions

bit 14 **Unimplemented:** Read as ‘0’

bit 13 **I2CSIDL:** I2Cx Stop in Idle Mode bit
1 = Discontinues module operation when the device enters an Idle mode
0 = Continues module operation in Idle mode

bit 12 **SCLREL:** SCLx Release Control bit (when operating as I²C slave)
1 = Releases SCLx clock
0 = Holds SCLx clock low (clock stretch)
If STREN = 1:
The bit is R/$\overline{W}$ (i.e., software may write ‘0’ to initiate stretch and write ‘1’ to release clock). Hardware is clear at the beginning of the slave transmission. Hardware is clear at the end of slave reception.
If STREN = 0:
The bit is R/S (i.e., software may only write ‘1’ to release clock). Hardware is clear at the beginning of slave transmission.

bit 11 **IPMIEN:** Intelligent Peripheral Management Interface (IPMI) Enable bit
1 = IPMI Support mode is enabled; all addresses are Acknowledged
0 = IPMI Support mode is disabled

bit 10 **A10M:** 10-Bit Slave Addressing bit
1 = I2CxADD is a 10-bit slave address
0 = I2CxADD is a 7-bit slave address

bit 9 **DISSLW:** Disable Slew Rate Control bit
1 = Slew rate control is disabled
0 = Slew rate control is enabled

bit 8 **SMEN:** SMBus Input Levels bit
1 = Enables I/O pin thresholds compliant with the SMBus specification
0 = Disables the SMBus input thresholds

bit 7 **GCEN:** General Call Enable bit (when operating as I²C slave)
1 = Enables interrupt when a general call address is received in the I2CxRSR (module is enabled for reception)
0 = General call address is disabled

bit 6 **STREN:** SCLx Clock Stretch Enable bit (when operating as I²C slave)
Used in conjunction with the SCLREL bit.
1 = Enables software or receives clock stretching
0 = Disables software or receives clock stretching

20.1.3 DATA SHIFT DIRECTION

The LENDIAN bit (CRCCON1<3>) is used to control the shift direction. By default, the CRC will shift data through the engine, MSb first. Setting LENDIAN (= 1) causes the CRC to shift data, LSb first. This setting allows better integration with various communication schemes and removes the overhead of reversing the bit order in software. Note that this only changes the direction of the data that is shifted into the engine. The result of the CRC calculation will still be a normal CRC result, not a reverse CRC result.

20.1.4 INTERRUPT OPERATION

The module generates an interrupt that is configurable by the user for either of two conditions. If CRCISEL is '0', an interrupt is generated when the VWORD<4:0> bits make a transition from a value of '1' to '0'. If CRCISEL is '1', an interrupt will be generated after the CRC operation finishes and the module sets the CRCGO bit to '0'. Manually setting CRCGO to '0' will not generate an interrupt.

20.1.5 TYPICAL OPERATION

To use the module for a typical CRC calculation:

1. Set the CRCEN bit to enable the module.
2. Configure the module for the desired operation:
   a) Program the desired polynomial using the CRCXORL and CRCXORH registers, and the PLEN<4:0> bits.
   b) Configure the data width and shift direction using the DWIDTHx and LENDIAN bits.
   c) Select the desired interrupt mode using the CRCISEL bit.
3. Preload the FIFO by writing to the CRCDATL and CRCDATH registers until the CRCFUL bit is set or no data is left.
4. Clear old results by writing 00h to CRCWDATL and CRCWDATH. CRCWDAT can also be left unchanged to resume a previously halted calculation.
5. Set the CRCGO bit to start calculation.
6. Write the remaining data into the FIFO as space becomes available.
7. When the calculation completes, CRCGO is automatically cleared. An interrupt will be generated if CRCISEL = 1.
8. Read CRCWDATL and CRCWDATH for the result of the calculation.

20.2 Registers

There are eight registers associated with the module:

- CRCCON1
- CRCCON2
- CRCXORL
- CRCXORH
- CRCDATL
- CRCDATH
- CRCWDATL
- CRCWDATH

The CRCCON1 and CRCCON2 registers (Register 20-1 and Register 20-2) control the operation of the module, and configure the various settings. The CRCXOR registers (Register 20-3 and Register 20-4) select the polynomial terms to be used in the CRC equation. The CRCDAT and CRCWDAT registers are each register pairs that serve as buffers for the double-word, input data and CRC processed output, respectively.

1 = Retention Regulator is not available
0 = Retention Regulator is available and controlled by the RETEN bit (RCON<12>) during Sleep

bit 1-0 **BOREN<1:0>:** Brown-out Reset Enable bits
11 = Brown-out Reset is enabled in hardware; SBOREN bit is disabled
10 = Brown-out Reset is enabled only while device is active and disabled in Sleep; SBOREN bit is disabled
01 = Brown-out Reset is controlled with the SBOREN bit setting
00 = Brown-out Reset is disabled in hardware; SBOREN bit is disabled

Note 1: This setting only applies to the “FV” devices. This bit is reserved and should be maintained as ‘1’ on “F” devices.
2: The MCLRE fuse can only be changed when using the V_{PP}-based ICSP™ mode entry. This prevents a user from accidentally locking out the device from the low-voltage test entry.
3: Refer to **Section 29.0 “Electrical Characteristics”** for BOR voltages.

26.2 On-Chip Voltage Regulator

All of the PIC24FV32KA304 family devices power their core digital logic at a nominal 3.0V. This may create an issue for designs that are required to operate at a higher typical voltage, as high as 5.0V. To simplify system design, all devices in the “FV” family incorporate an on-chip regulator that allows the device to run its core logic from VDD.

The regulator is always enabled and provides power to the core from the other VDD pins. A low-ESR capacitor (such as ceramic) must be connected to the VCAP pin (Figure 26-1). This helps to maintain the stability of the regulator. The recommended value for the filter capacitor is discussed in **Section 2.4 “Voltage Regulator Pin (VCAP)”**, and in **Section 29.1 “DC Characteristics”**.

For “F” devices, the regulator is disabled. Instead, core logic is powered directly from VDD. This allows the devices to operate at an overall lower allowable voltage range (1.8V-3.6V).

26.2.1 VOLTAGE REGULATOR TRACKING MODE AND LOW-VOLTAGE DETECTION

For all PIC24FV32KA304 devices, the on-chip regulator provides a constant voltage of 3.2V nominal to the digital core logic. The regulator can provide this level from a VDD of about 3.2V, all the way up to the device’s VDDMAX. It does not have the capability to boost VDD levels below 3.2V. In order to prevent “brown-out” conditions when the voltage drops too low for the regulator, the regulator enters Tracking mode. In Tracking mode, the regulator output follows VDD with a typical voltage drop of 150 mV.

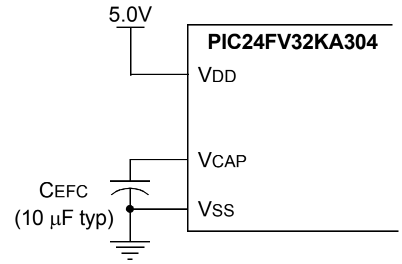
When the device enters Tracking mode, it is no longer possible to operate at full speed. To provide information about when the device enters Tracking mode, the on-chip regulator includes a simple, High/Low-Voltage Detect (HLVD) circuit. When VDD drops below full-speed operating voltage, the circuit sets the High/Low-Voltage Detect Interrupt Flag, HLVDIF (IFS4<8>). This can be used to generate an interrupt and put the application into a low-power operational mode or trigger an orderly shutdown. Maximum device speeds as a function of VDD are shown in **Section 29.1 “DC Characteristics”**, in Figure 29-1 and Figure 29-1.

26.2.2 ON-CHIP REGULATOR AND POR

For PIC24FV32KA304 devices, it takes a brief time, designated as TPM, for the Voltage Regulator to generate a stable output. During this time, code execution is disabled. TPM (DC Specification SY71) is applied every time the device resumes operation after any power-down, including Sleep mode.

FIGURE 26-1: CONNECTIONS FOR THE ON-CHIP REGULATOR

Regulator Enabled(1):



Note 1: These are typical operating voltages. Refer to **Section 29.0 “Electrical Characteristics”** for the full operating ranges of VDD.

26.3 Watchdog Timer (WDT)

For the PIC24FV32KA304 family of devices, the WDT is driven by the LPRC oscillator. When the WDT is enabled, the clock source is also enabled.

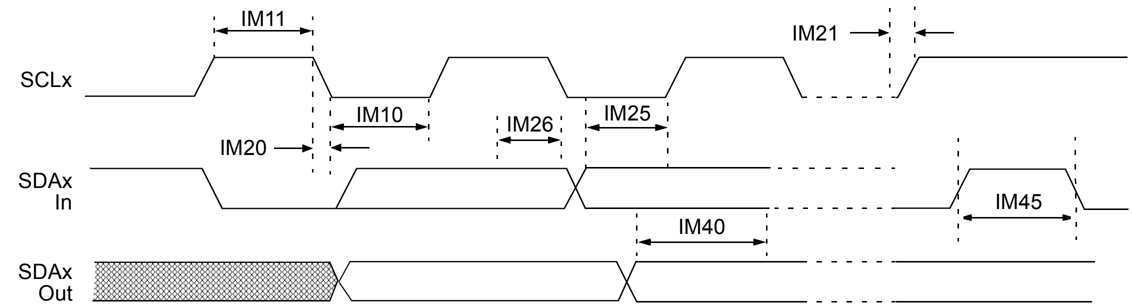
The nominal WDT clock source from LPRC is 31 kHz. This feeds a prescaler that can be configured for either 5-bit (divide-by-32) or 7-bit (divide-by-128) operation. The prescaler is set by the FWPSA Configuration bit. With a 31 kHz input, the prescaler yields a nominal WDT time-out period (TWDT) of 1 ms in 5-bit mode or 4 ms in 7-bit mode.

A variable postscaler divides down the WDT prescaler output and allows for a wide range of time-out periods. The postscaler is controlled by the Configuration bits, WDTPS<3:0> (FWDT<3:0>), which allow the selection of a total of 16 settings, from 1:1 to 1:32,768. Using the prescaler and postscaler time-out periods, ranging from 1 ms to 131 seconds, can be achieved.

The WDT, prescaler and postscaler are reset:

- On any device Reset
- On the completion of a clock switch, whether invoked by software (i.e., setting the OSWEN bit after changing the NOSCx bits) or by hardware (i.e., Fail-Safe Clock Monitor)
- When a `PWRSAV` instruction is executed (i.e., Sleep or Idle mode is entered)
- When the device exits Sleep or Idle mode to resume normal operation
- By a `CLRWDT` instruction during normal execution

FIGURE 29-13: I²C™ BUS DATA TIMING CHARACTERISTICS (MASTER MODE)



Note: Refer to Figure 29-3 for load conditions.

TABLE 29-32: I²C™ BUS DATA TIMING REQUIREMENTS (MASTER MODE)

AC CHARACTERISTICS				Standard Operating Conditions: 2.0V to 3.6V (unless otherwise stated) Operating temperature -40°C ≤ T_A ≤ +85°C for Industrial -40°C ≤ T_A ≤ +125°C for Extended
