AMD Xilinx - XC3S500E-4FT256I Datasheet

Welcome to E-XFL.COM

Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Active
Number of LABs/CLBs	1164
Number of Logic Elements/Cells	10476
Total RAM Bits	368640
Number of I/O	190
Number of Gates	500000
Voltage - Supply	1.14V ~ 1.26V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 100°C (TJ)
Package / Case	256-LBGA
Supplier Device Package	256-FTBGA (17x17)
Purchase URL	https://www.e-xfl.com/product-detail/xilinx/xc3s500e-4ft256i

Configuration

Spartan-3E FPGAs are programmed by loading configuration data into robust, reprogrammable, static CMOS configuration latches (CCLs) that collectively control all functional elements and routing resources. The FPGA's configuration data is stored externally in a PROM or some other non-volatile medium, either on or off the board. After applying power, the configuration data is written to the FPGA using any of seven different modes:

- Master Serial from a Xilinx Platform Flash PROM
- Serial Peripheral Interface (SPI) from an industry-standard SPI serial Flash
- Byte Peripheral Interface (BPI) Up or Down from an industry-standard x8 or x8/x16 parallel NOR Flash
- Slave Serial, typically downloaded from a processor
- Slave Parallel, typically downloaded from a processor
- Boundary Scan (JTAG), typically downloaded from a processor or system tester.

Furthermore, Spartan-3E FPGAs support MultiBoot configuration, allowing two or more FPGA configuration bitstreams to be stored in a single parallel NOR Flash. The FPGA application controls which configuration to load next and when to load it.

I/O Capabilities

The Spartan-3E FPGA SelectIO interface supports many popular single-ended and differential standards. Table 2 shows the number of user I/Os as well as the number of differential I/O pairs available for each device/package combination.

Spartan-3E FPGAs support the following single-ended standards:

- 3.3V low-voltage TTL (LVTTL)
- Low-voltage CMOS (LVCMOS) at 3.3V, 2.5V, 1.8V, 1.5V, or 1.2V
- 3V PCI at 33 MHz, and in some devices, 66 MHz
- HSTL I and III at 1.8V, commonly used in memory applications
- SSTL I at 1.8V and 2.5V, commonly used for memory applications

Spartan-3E FPGAs support the following differential standards:

- LVDS
- Bus LVDS
- mini-LVDS
- RSDS
- Differential HSTL (1.8V, Types I and III)
- Differential SSTL (2.5V and 1.8V, Type I)
- 2.5V LVPECL inputs

Table 2: **Available User I/Os and Differential (Diff) I/O Pairs**

Package	VQ100 VQG100		CP132 CPG132		TQ144 TQG144		PQ208 PQG208		FT256 FTG256		FG320 FGG320		FG400 FGG400		FG484 FGG484

Notes:

1. All Spartan-3E devices provided in the same package are pin-compatible as further described in Module 4, Pinout Descriptions.
2. The number shown in **bold** indicates the maximum number of I/O and input-only pins. The number shown in (*italics*) indicates the number of input-only pins.
3. The XC3S500E is available in the VQG100 Pb-free package and not the standard VQ100. The VQG100 and VQ100 pin-outs are identical and general references to the VQ100 will apply to the XC3S500E.

Package Marking

Figure 2 provides a top marking example for Spartan-3E FPGAs in the quad-flat packages. Figure 3 shows the top marking for Spartan-3E FPGAs in BGA packages except the 132-ball chip-scale package (CP132 and CPG132). The markings for the BGA packages are nearly identical to those for the quad-flat packages, except that the marking is rotated with respect to the ball A1 indicator. Figure 4 shows the top marking for Spartan-3E FPGAs in the CP132 and CPG132 packages.

On the QFP and BGA packages, the optional numerical Stepping Code follows the Lot Code.

The "5C" and "4I" part combinations can have a dual mark of "5C/4I". Devices with a single mark are only guaranteed for the marked speed grade and temperature range. All "5C" and "4I" part combinations use the Stepping 1 production silicon.

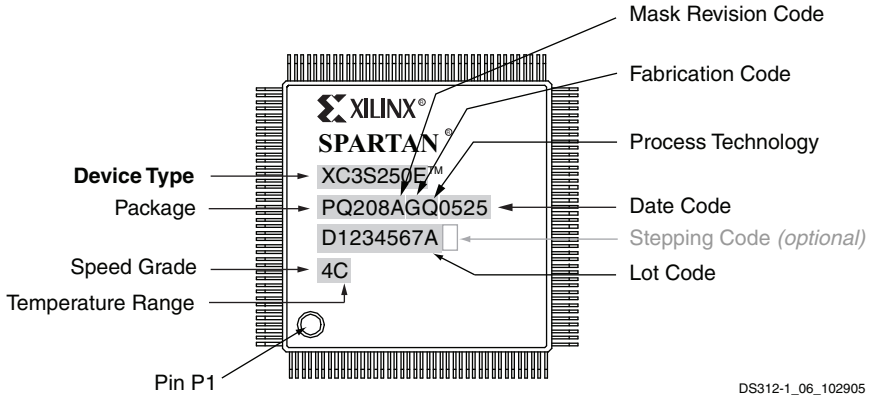

Figure 2: **Spartan-3E QFP Package Marking Example**

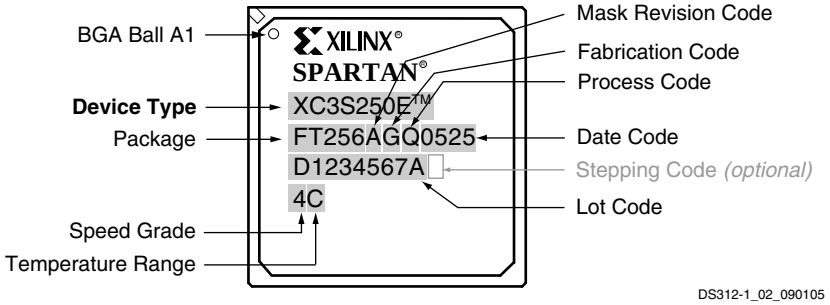

Figure 3: **Spartan-3E BGA Package Marking Example**

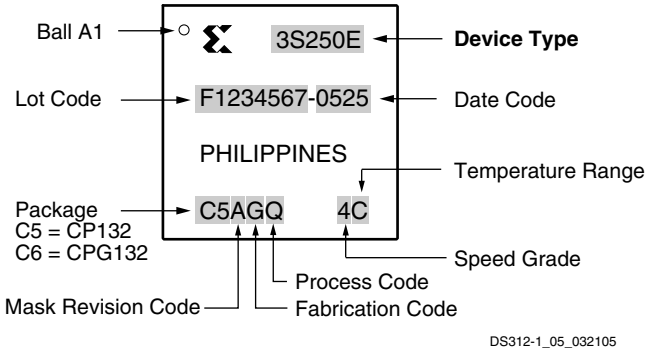

Figure 4: **Spartan-3E CP132 and CPG132 Package Marking Example**

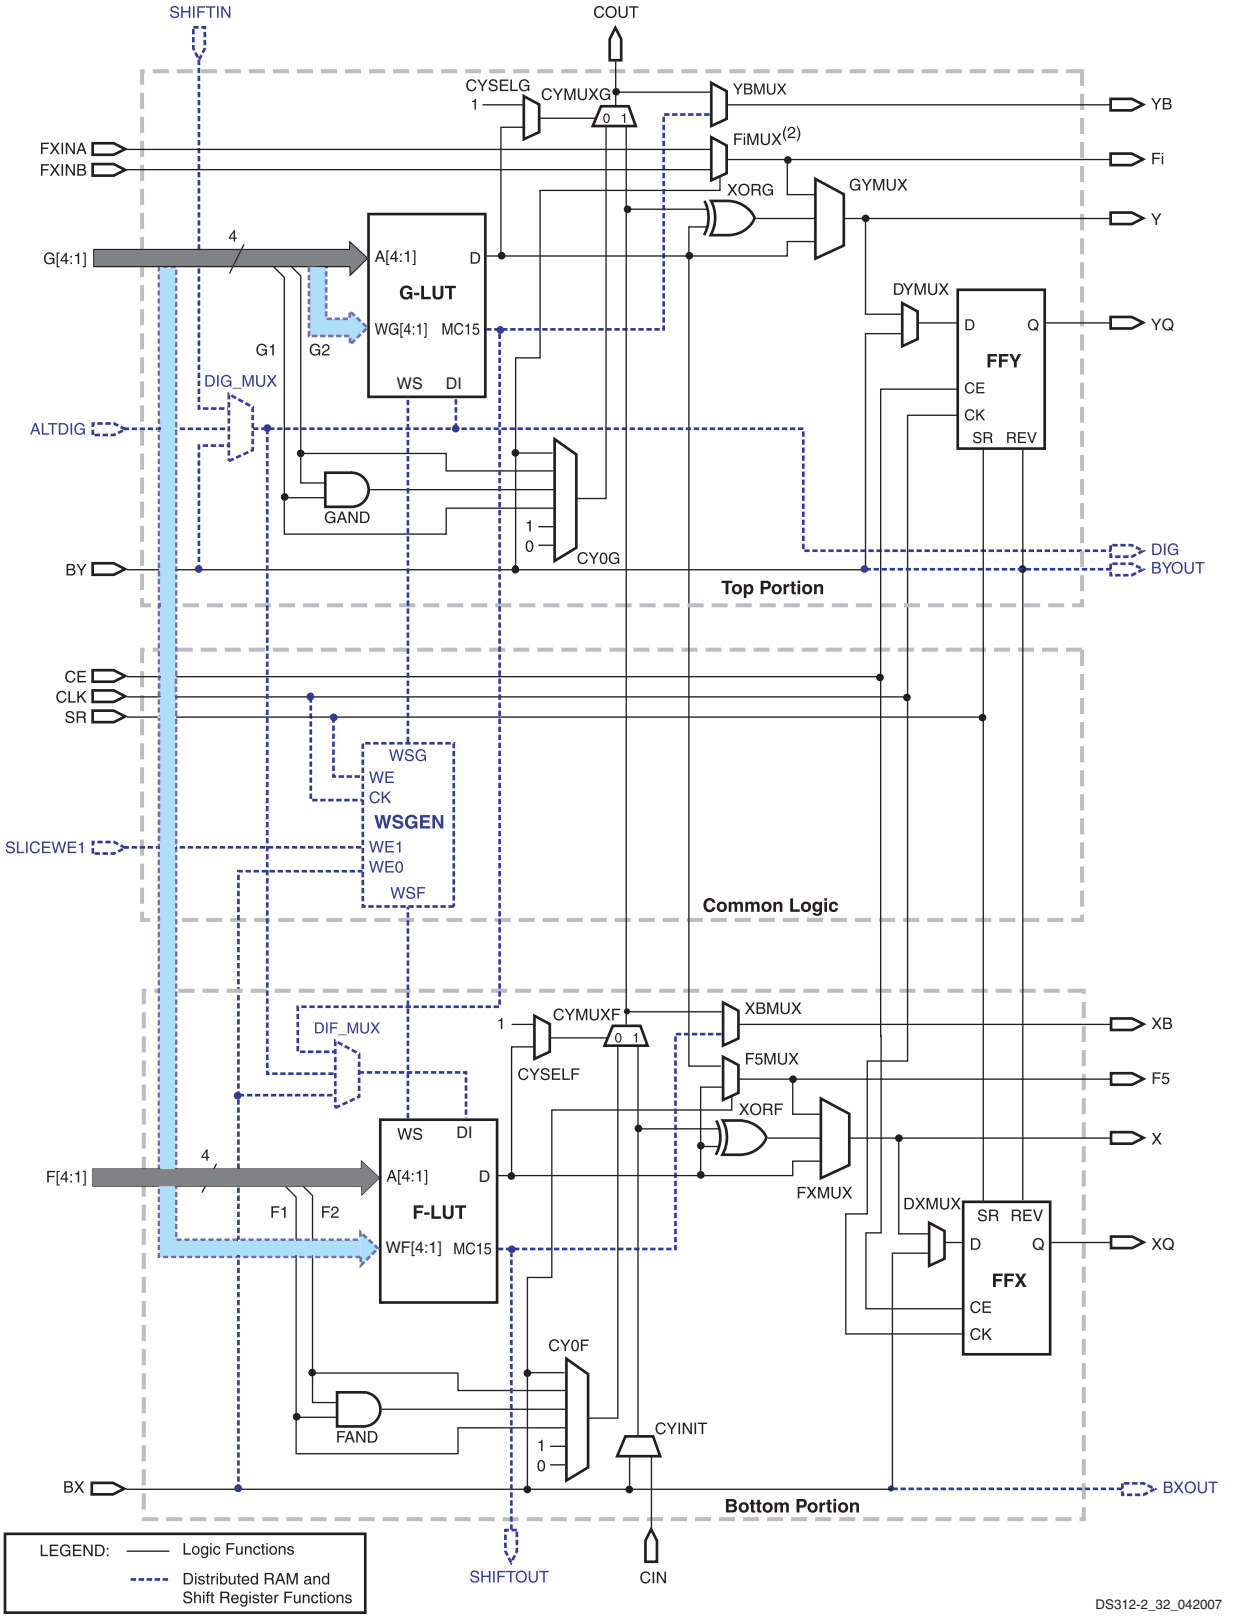

Notes:

1. Options to invert signal polarity as well as other options that enable lines for various functions are not shown.
2. The index i can be 6, 7, or 8, depending on the slice. The upper SLICEL has an F8MUX, and the upper SLICEM has an F7MUX. The lower SLICEL and SLICEM both have an F6MUX.

Figure 15: **Simplified Diagram of the Left-Hand SLICEM**

Table 10: **Slice Inputs and Outputs *(Cont'd)***

Name	Location	Direction	Description
SHIFTOUT	SLICEM Bottom	Output	Shift data output from F-LUT RAM
CIN	SLICEL/M Bottom	Input	Carry chain input
COUT	SLICEL/M Top	Output	Carry chain output
X	SLICEL/M Bottom	Output	Combinatorial output
Y	SLICEL/M Top	Output	Combinatorial output
XB	SLICEL/M Bottom	Output	Combinatorial output from carry or F-LUT SRL16 (SLICEM)
YB	SLICEL/M Top	Output	Combinatorial output from carry or G-LUT SRL16 (SLICEM)
XQ	SLICEL/M Bottom	Output	FFX output
YQ	SLICEL/M Top	Output	FFY output

Main Logic Paths

Central to the operation of each slice are two nearly identical data paths at the top and bottom of the slice. The description that follows uses names associated with the bottom path. (The top path names appear in parentheses.) The basic path originates at an interconnect switch matrix outside the CLB. See Interconnect for more information on the switch matrix and the routing connections.

Four lines, F1 through F4 (or G1 through G4 on the upper path), enter the slice and connect directly to the LUT. Once inside the slice, the lower 4-bit path passes through a LUT 'F' (or 'G') that performs logic operations. The LUT Data output, 'D', offers five possible paths:

1. Exit the slice via line "X" (or "Y") and return to interconnect.
2. Inside the slice, "X" (or "Y") serves as an input to the DXMUX (or DYMUX) which feeds the data input, "D", of the FFX (or FFY) storage element. The "Q" output of the storage element drives the line XQ (or YQ) which exits the slice.
3. Control the CYMUXF (or CYMUXG) multiplexer on the carry chain.
4. With the carry chain, serve as an input to the XORF (or XORG) exclusive-OR gate that performs arithmetic operations, producing a result on "X" (or "Y").
5. Drive the multiplexer F5MUX to implement logic functions wider than four bits. The "D" outputs of both the F-LUT and G-LUT serve as data inputs to this multiplexer.

In addition to the main logic paths described above, there are two bypass paths that enter the slice as BX and BY. Once inside the FPGA, BX in the bottom half of the slice (or BY in the top half) can take any of several possible branches:

1. Bypass both the LUT and the storage element, and then exit the slice as BXOUT (or BYOUT) and return to interconnect.
2. Bypass the LUT, and then pass through a storage element via the D input before exiting as XQ (or YQ).
3. Control the wide function multiplexer F5MUX (or FiMUX).
4. Via multiplexers, serve as an input to the carry chain.
5. Drive the DI input of the LUT.
6. BY can control the REV inputs of both the FFY and FFX storage elements. See Storage Element Functions.
7. Finally, the DIG_MUX multiplexer can switch BY onto the DIG line, which exits the slice.

The control inputs CLK, CE, SR, BX and BY have programmable polarity. The LUT inputs do not need programmable polarity because their function can be inverted inside the LUT.

The sections that follow provide more detail on individual functions of the slice.

Look-Up Tables

The Look-Up Table or LUT is a RAM-based function generator and is the main resource for implementing logic functions. Furthermore, the LUTs in each SLICEM pair can be configured as Distributed RAM or a 16-bit shift register, as described later.

Each of the two LUTs (F and G) in a slice have four logic inputs (A1-A4) and a single output (D). Any four-variable Boolean logic operation can be implemented in one LUT. Functions with more inputs can be implemented by cascading LUTs or by using the wide function multiplexers that are described later.

The output of the LUT can connect to the wide multiplexer logic, the carry and arithmetic logic, or directly to a CLB output or to the CLB storage element. See Figure 18.

initialized distributed RAM contents are not disturbed during the configuration process.

The distributed RAM is useful for smaller amounts of memory. Larger memory requirements can use the dedicated 18Kbit RAM blocks (see Block RAM).

Shift Registers

For additional information, refer to the “Using Look-Up Tables as Shift Registers (SRL16)” chapter in UG331.

It is possible to program each SLICEM LUT as a 16-bit shift register (see Figure 28). Used in this way, each LUT can delay serial data anywhere from 1 to 16 clock cycles without using any of the dedicated flip-flops. The resulting programmable delays can be used to balance the timing of data pipelines.

The SLICEM LUTs cascade from the G-LUT to the F-LUT through the DIFMUX (see Figure 15). SHIFTIN and SHIFTOUT lines cascade a SLICEM to the SLICEM below to form larger shift registers. The four SLICEM LUTs of a single CLB can be combined to produce delays up to 64 clock cycles. It is also possible to combine shift registers across more than one CLB.

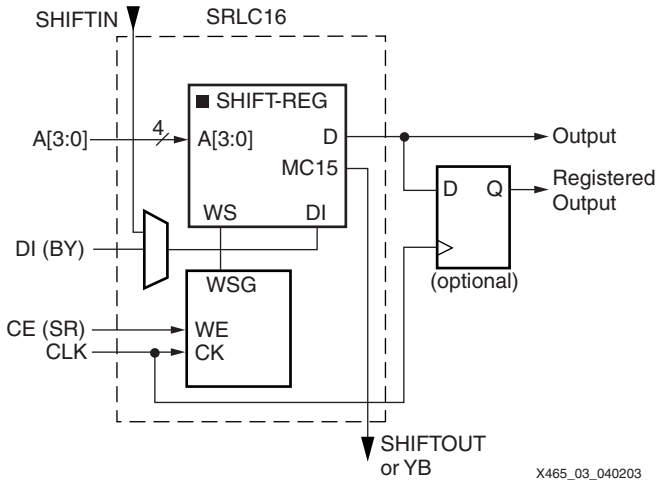

Figure 28: **Logic Cell SRL16 Structure**

Each shift register provides a shift output MC15 for the last bit in each LUT, in addition to providing addressable access to any bit in the shift register through the normal D output. The address inputs A[3:0] are the same as the distributed RAM address lines, which come from the LUT inputs F[4:1] or G[4:1]. At the end of the shift register, the CLB flip-flop can be used to provide one more shift delay for the addressable bit.

The shift register element is known as the SRL16 (Shift Register LUT 16-bit), with a ‘C’ added to signify a cascade ability (Q15 output) and ‘E’ to indicate a Clock Enable. See Figure 29 for an example of the SRLC16E component.

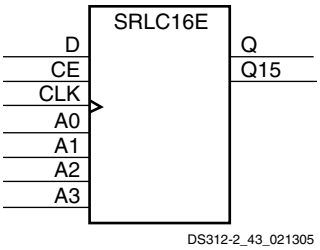

Figure 29: **SRL16 Shift Register Component with Cascade and Clock Enable**

The functionality of the shift register is shown in Table 20. The SRL16 shifts on the rising edge of the clock input when the Clock Enable control is High. This shift register cannot be initialized either during configuration or during operation except by shifting data into it. The clock enable and clock inputs are shared between the two LUTs in a SLICEM. The clock enable input is automatically kept active if unused.

Table 20: **SRL16 Shift Register Function**

Inputs				Outputs	
Am	**CLK**	**CE**	**D**	**Q**	**Q15**
Am	X	0	X	Q[Am]	Q[15]
Am	↑	1	D	Q[Am-1]	Q[15]

Notes:

1. m = 0, 1, 2, 3.

Block RAM

For additional information, refer to the “Using Block RAM” chapter in UG331.

Spartan-3E devices incorporate 4 to 36 dedicated block RAMs, which are organized as dual-port configurable 18 Kbit blocks. Functionally, the block RAM is identical to the Spartan-3 architecture block RAM. Block RAM synchronously stores large amounts of data while distributed RAM, previously described, is better suited for buffering small amounts of data anywhere along signal paths. This section describes basic block RAM functions.

Each block RAM is configurable by setting the content’s initial values, default signal value of the output registers, port aspect ratios, and write modes. Block RAM can be used in single-port or dual-port modes.

Arrangement of RAM Blocks on Die

The block RAMs are located together with the multipliers on the die in one or two columns depending on the size of the device. The XC3S100E has one column of block RAM. The Spartan-3E devices ranging from the XC3S250E to XC3S1600E have two columns of block RAM. Table 21 shows the number of RAM blocks, the data storage capacity, and the number of columns for each device. Row(s) of CLBs are located above and below each block RAM column.

Table 21: **Number of RAM Blocks by Device**

Device	Total Number of RAM Blocks	Total Addressable Locations (bits)	Number of Columns
XC3S100E	4	73,728	1
XC3S250E	12	221,184	2
XC3S500E	20	368,640	2
XC3S1200E	28	516,096	2
XC3S1600E	36	663,552	2

Immediately adjacent to each block RAM is an embedded 18x18 hardware multiplier. The upper 16 bits of the block RAM's Port A Data input bus are shared with the upper 16 bits of the A multiplicand input bus of the multiplier. Similarly, the upper 16 bits of Port B's data input bus are shared with the B multiplicand input bus of the multiplier.

The Internal Structure of the Block RAM

The block RAM has a dual port structure. The two identical data ports called A and B permit independent access to the common block RAM, which has a maximum capacity of 18,432 bits, or 16,384 bits with no parity bits (see parity bits description in Table 22). Each port has its own dedicated set of data, control, and clock lines for synchronous read and write operations. There are four basic data paths, as shown in Figure 30:

1. Write to and read from Port A
2. Write to and read from Port B
3. Data transfer from Port A to Port B
4. Data transfer from Port B to Port A

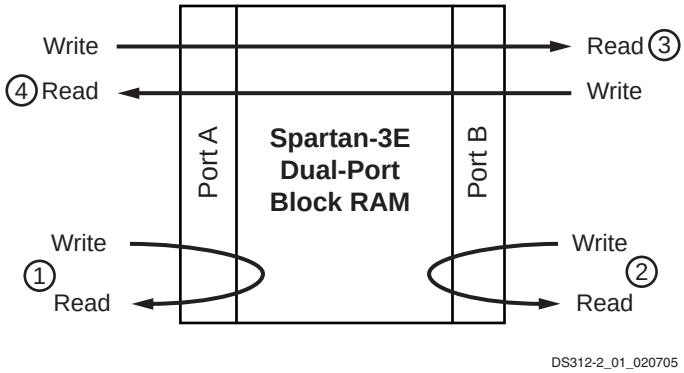

Figure 30: **Block RAM Data Paths**

Number of Ports

A choice among primitives determines whether the block RAM functions as dual- or single-port memory. A name of the form RAMB16_S[w_A]_S[w_B] calls out the dual-port primitive, where the integers w_A and w_B specify the total data path width at ports A and B, respectively. Thus, a RAMB16_S9_S18 is a dual-port RAM with a 9-bit Port A and an 18-bit Port B. A name of the form RAMB16_S[w] identifies the single-port primitive, where the integer w specifies the total data path width of the lone port A. A RAMB16_S18 is a single-port RAM with an 18-bit port.

Port Aspect Ratios

Each port of the block RAM can be configured independently to select a number of different possible widths for the data input (DI) and data output (DO) signals as shown in Table 22.

Configuration Bitstream Image Sizes

A specific Spartan-3E part type always requires a constant number of configuration bits, regardless of design complexity, as shown in Table 45. The configuration file size for a multiple-FPGA daisy-chain design roughly equals the sum of the individual file sizes.

Table 45: **Number of Bits to Program a Spartan-3E FPGA (Uncompressed Bitstreams)**

Spartan-3E FPGA	Number of Configuration Bits
XC3S100E	581,344
XC3S250E	1,353,728
XC3S500E	2,270,208
XC3S1200E	3,841,184
XC3S1600E	5,969,696

Pin Behavior During Configuration

For additional information, refer to the "Configuration Pins and Behavior during Configuration" chapter in UG332.

Table 46 shows how various pins behave during the FPGA configuration process. The actual behavior depends on the values applied to the M2, M1, and M0 mode select pins and the HSWAP pin. The mode select pins determine which of the I/O pins are borrowed during configuration and how they function. In JTAG configuration mode, no user-I/O pins are borrowed for configuration.

All user-I/O pins, input-only pins, and dual-purpose pins that are not actively involved in the currently-select configuration mode are high impedance (floating, three-stated, Hi-Z) during the configuration process. These pins are indicated in Table 46 as gray shaded table entries or cells.

The HSWAP input controls whether all user-I/O pins, input-only pins, and dual-purpose pins have a pull-up resistor to the supply rail or not. When HSWAP is Low, each pin has an internal pull-up resistor that is active throughout configuration. After configuration, pull-up and pull-down resistors are available in the FPGA application as described in Pull-Up and Pull-Down Resistors.

The yellow-shaded table entries or cells represent pins where the pull-up resistor is always enabled during configuration, regardless of the HSWAP input. The post-configuration behavior of these pins is defined by Bitstream Generator options as defined in Table 69.

Table 46: **Pin Behavior during Configuration**

Pin Name	Master Serial	SPI (Serial Flash)	BPI (Parallel NOR Flash)	JTAG	Slave Parallel	Slave Serial	I/O Bank[3]
IO* (user-I/O) IP* (input-only)							-

WRITER NOTE: Many of the URLs in this table are obsolete or otherwise broken.

Daisy-Chaining

If the application requires multiple FPGAs with different configurations, then configure the FPGAs using a daisy chain, as shown in Figure 57. Daisy-chaining from a single SPI serial Flash PROM is supported in Stepping 1 devices. It is not supported in Stepping 0 devices. Use SPI Flash mode (M[2:0] = <0:0:1>) for the FPGA connected to the Platform Flash PROM and Slave Serial mode (M[2:0] = <1:1:1>) for all other FPGAs in the daisy-chain. After the master FPGA—the FPGA on the left in the diagram—finishes loading its configuration data from the SPI Flash PROM, the master device uses its DOUT output pin to supply data to the next device in the daisy-chain, on the falling CCLK edge.

Design Note

SPI mode daisy chains are supported only in Stepping 1 silicon versions.

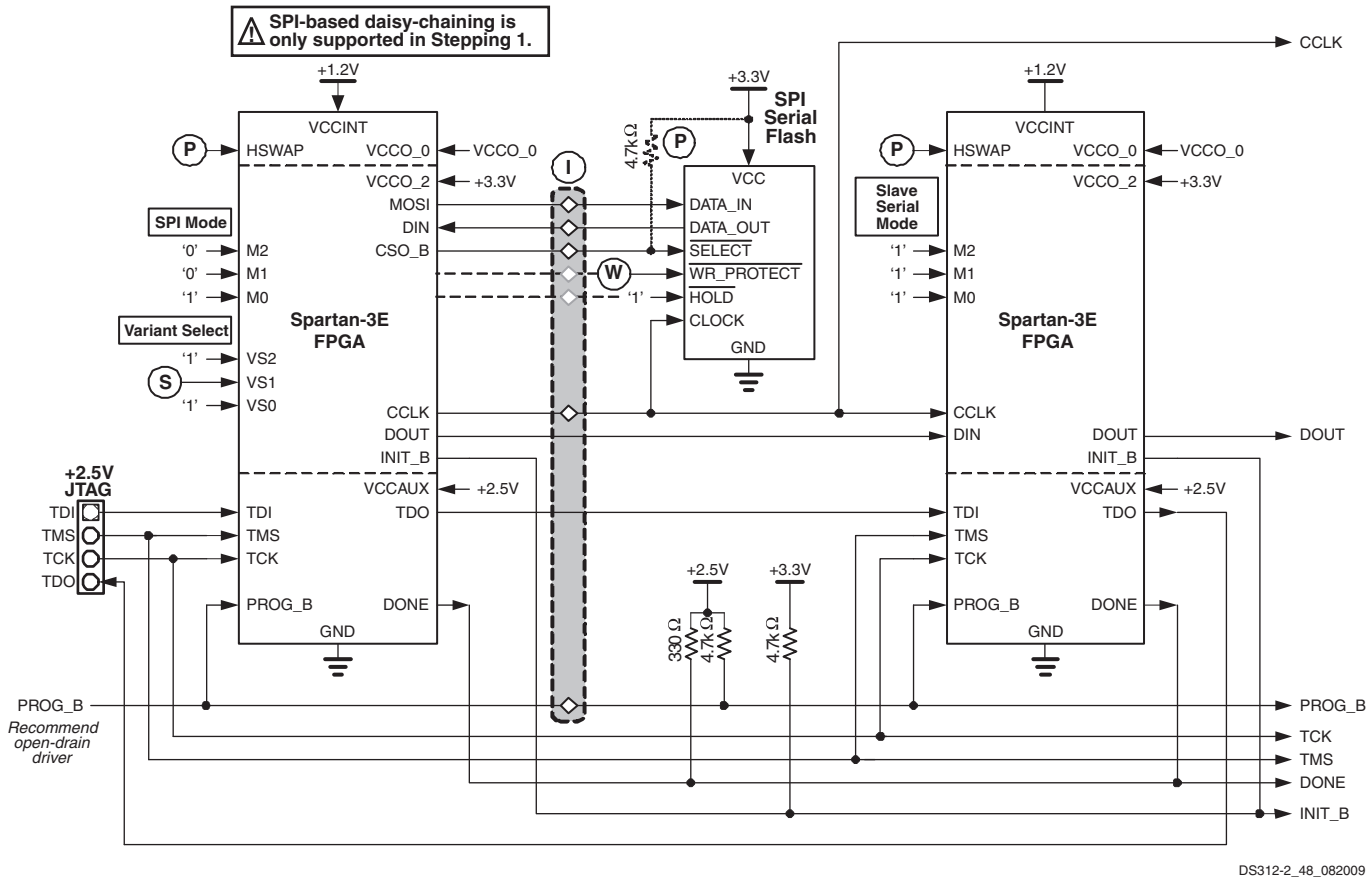

Figure 57: **Daisy-Chaining from SPI Flash Mode (Stepping 1)**

Programming Support

For successful daisy-chaining, the ***DONE_cycle*** configuration option must be set to cycle 5 or sooner. The default cycle is 4. See Table 69 and the Start-Up section for additional information.

(I) In production applications, the SPI Flash PROM is usually pre-programmed before it is mounted on the printed circuit board. The Xilinx ISE development software produces industry-standard programming files that can be used with third-party gang programmers. Consult your specific SPI Flash vendor for recommended production programming solutions.

In-system programming support is available from some third-party PROM programmers using a socket adapter with attached wires. To gain access to the SPI Flash signals, drive the FPGA's PROG_B input Low with an open-drain driver. This action places all FPGA I/O pins, including those attached to the SPI Flash, in high-impedance (Hi-Z). If the HSWAP input is Low, the I/Os have pull-up resistors to the V_{CCO} input on their respective I/O bank. The external programming hardware then has direct access to the SPI Flash pins. The programming access points are highlighted in the gray box in Figure 53, Figure 54, and Figure 57.

Beginning with the Xilinx ISE 8.2i software release, the iMPACT programming utility provides direct, in-system prototype programming support for STMicro M25P-series

Readback

FPGA configuration data can be read back using either the Slave Parallel or JTAG mode. This function is disabled if the Bitstream Generator ***Security*** option is set to either ***Level1*** or ***Level2***.

Along with the configuration data, it is possible to read back the contents of all registers and distributed RAM.

To synchronously control when register values are captured for readback, use the CAPTURE_SPARTAN3 library primitive, which applies for both Spartan-3 and Spartan-3E FPGA families.

The Readback feature is available in most Spartan-3E FPGA product options, as indicated in Table 68. The Readback feature is not available in the XC3S1200E and XC3S1600E FPGAs when using the -4 speed grade in the Commercial temperature grade. Similarly, block RAM Readback support is not available in the -4 speed grade, Commercial temperature devices. If Readback is required in an XC3S1200E or XC3S1600E FPGA, or if block RAM Readback is required on any Spartan-3E FPGA, upgrade to either the Industrial temperature grade version or the -5 speed grade.

The Xilinx iMPACT programming software uses the Readback feature for its optional Verify and Readback operations. The Xilinx ChipScope™ software presently does not use Readback but may in future updates.

Table 68: **Readback Support in Spartan-3E FPGAs**

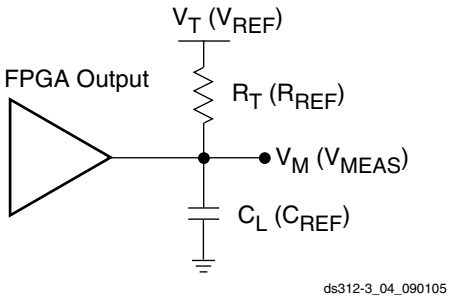
Temperature Range	Commercial		Industrial
Speed Grade	**-4**	**-5**	**-4**
Block RAM Readback			
All Spartan-3E FPGAs	No	Yes	Yes
General Readback (registers, distributed RAM)			
XC3S100E	Yes	Yes	Yes
XC3S250E	Yes	Yes	Yes
XC3S500E	Yes	Yes	Yes
XC3S1200E	No	Yes	Yes
XC3S1600E	No	Yes	Yes

Timing Measurement Methodology

When measuring timing parameters at the programmable I/Os, different signal standards call for different test conditions. Table 95 lists the conditions to use for each standard.

The method for measuring Input timing is as follows: A signal that swings between a Low logic level of V_L and a High logic level of V_H is applied to the Input under test. Some standards also require the application of a bias voltage to the V_{REF} pins of a given bank to properly set the input-switching threshold. The measurement point of the Input signal (V_M) is commonly located halfway between V_L and V_H.

The Output test setup is shown in Figure 72. A termination voltage V_T is applied to the termination resistor R_T, the other end of which is connected to the Output. For each standard, R_T and V_T generally take on the standard values recommended for minimizing signal reflections. If the standard does not ordinarily use terminations (e.g., LVCMOS, LVTTL), then R_T is set to 1MΩ to indicate an open connection, and V_T is set to zero. The same measurement point (V_M) that was used at the Input is also used at the Output.



Notes:

1. The names shown in parentheses are used in the IBIS file.

Figure 72: **Output Test Setup**

Table 95: **Test Methods for Timing Measurement at I/Os**

Signal Standard (IOSTANDARD)		Inputs			Outputs		Inputs and Outputs
		V_{REF} (V)	V_L (V)	V_H (V)	R_T (Ω)	V_T (V)	V_M (V)
Single-Ended

Simultaneously Switching Output Guidelines

This section provides guidelines for the recommended maximum allowable number of Simultaneous Switching Outputs (SSOs). These guidelines describe the maximum number of user I/O pins of a given output signal standard that should simultaneously switch in the same direction, while maintaining a safe level of switching noise. Meeting these guidelines for the stated test conditions ensures that the FPGA operates free from the adverse effects of ground and power bounce.

Ground or power bounce occurs when a large number of outputs simultaneously switch in the same direction. The output drive transistors all conduct current to a common voltage rail. Low-to-High transitions conduct to the V_{CCO} rail; High-to-Low transitions conduct to the GND rail. The resulting cumulative current transient induces a voltage difference across the inductance that exists between the die pad and the power supply or ground return. The inductance is associated with bonding wires, the package lead frame, and any other signal routing inside the package. Other variables contribute to SSO noise levels, including stray inductance on the PCB as well as capacitive loading at receivers. Any SSO-induced voltage consequently affects internal switching noise margins and ultimately signal quality.

Table 96 and Table 97 provide the essential SSO guidelines. For each device/package combination, Table 96 provides the number of equivalent V_{CCO}/GND pairs. The equivalent number of pairs is based on characterization and might not match the physical number of pairs. For each output signal standard and drive strength, Table 97 recommends the maximum number of SSOs, switching in the same direction, allowed per V_{CCO}/GND pair within an I/O bank. The guidelines in Table 97 are categorized by package style. Multiply the appropriate numbers from Table 96 and Table 97 to calculate the maximum number of SSOs allowed within an I/O bank. Exceeding these SSO guidelines might result in increased power or ground bounce, degraded signal integrity, or increased system jitter.

SSO_{MAX}/IO Bank = Table 96 x Table 97

The recommended maximum SSO values assumes that the FPGA is soldered on the printed circuit board and that the board uses sound design practices. The SSO values do not apply for FPGAs mounted in sockets, due to the lead inductance introduced by the socket.

The number of SSOs allowed for quad-flat packages (VQ, TQ, PQ) is lower than for ball grid array packages (FG) due to the larger lead inductance of the quad-flat packages. The results for chip-scale packaging (CP132) are better than quad-flat packaging but not as high as for ball grid array packaging. Ball grid array packages are recommended for applications with a large number of simultaneously switching outputs.

Table 96: **Equivalent V_{CCO}/GND Pairs per Bank**

Device	Package Style *(including Pb-free)*							
	VQ100	CP132	TQ144	PQ208	FT256	FG320	FG400	FG484
XC3S100E	2	2	2	-	-	-	-	-
XC3S250E	2	2	2	3	4	-	-	-
XC3S500E	2	2	-	3	4	5	-	-
XC3S1200E	-	-	-	-	4	5	6	-
XC3S1600E	-	-	-	-	-	5	6	7

Table 107: **Switching Characteristics for the DFS**

Symbol	Description		Device	Speed Grade				Units
				-5		-4		
				Min	Max	Min	Max	
Output Frequency Ranges								
CLKOUT_FREQ_FX_LF	Frequency for the CLKFX and CLKFX180 outputs, low frequencies	Stepping 0	XC3S100E XC3S250E XC3S500E XC3S1600E	N/A	N/A	5	90	MHz
CLKOUT_FREQ_FX_HF	Frequency for the CLKFX and CLKFX180 outputs, high frequencies					220	307	MHz
CLKOUT_FREQ_FX	Frequency for the CLKFX and CLKFX180 outputs	Stepping 0	XC3S1200E			5	307	MHz
		Stepping 1	All	5	333		311	MHz
Output Clock Jitter(2,3)								
CLKOUT_PER_JITT_FX	Period jitter at the CLKFX and CLKFX180 outputs.		All	Typ	Max	Typ	Max	
		CLKIN ≤ 20 MHz		Note 6				ps
		CLKIN > 20 MHz		±[1% of CLKFX period + 100]	±[1% of CLKFX period + 200]	±[1% of CLKFX period + 100]	±[1% of CLKFX period + 200]	ps
Duty Cycle(4,5)								
CLKOUT_DUTY_CYCLE_FX	Duty cycle precision for the CLKFX and CLKFX180 outputs, including the BUFGMUX and clock tree duty-cycle distortion		All	-	±[1% of CLKFX period + 400]	-	±[1% of CLKFX period + 400]	ps
Phase Alignment(5)								
CLKOUT_PHASE_FX	Phase offset between the DFS CLKFX output and the DLL CLK0 output when both the DFS and DLL are used		All	-	±200	-	±200	ps
CLKOUT_PHASE_FX180	Phase offset between the DFS CLKFX180 output and the DLL CLK0 output when both the DFS and DLL are used		All	-	±[1% of CLKFX period + 300]	-	±[1% of CLKFX period + 300]	ps
Lock Time								
LOCK_FX(2)	The time from deassertion at the DCM's Reset input to the rising transition at its LOCKED output. The DFS asserts LOCKED when the CLKFX and CLKFX180 signals are valid. If using both the DLL and the DFS, use the longer locking time.	5 MHz ≤ F_{CLKIN} ≤ 15 MHz	All	-	5	-	5	ms
		F_{CLKIN} > 15 MHz		-	450	-	450	µs

Notes:

1. The numbers in this table are based on the operating conditions set forth in Table 77 and Table 106.
2. For optimal jitter tolerance and faster lock time, use the CLKIN_PERIOD attribute.
3. Maximum output jitter is characterized within a reasonable noise environment (150 ps input period jitter, 40 SSOs and 25% CLB switching). Output jitter strongly depends on the environment, including the number of SSOs, the output drive strength, CLB utilization, CLB switching activities, switching frequency, power supply and PCB design. The actual maximum output jitter depends on the system application.
4. The CLKFX and CLKFX180 outputs always have an approximate 50% duty cycle.
5. Some duty-cycle and alignment specifications include 1% of the CLKFX output period or 0.01 UI.
   Example: The data sheet specifies a maximum jitter of ±[1% of CLKFX period + 300]. Assume the CLKFX output frequency is 100 MHz. The equivalent CLKFX period is 10 ns and 1% of 10 ns is 0.1 ns or 100 ps. According to the data sheet, the maximum jitter is ±[100 ps + 300 ps] = ±400 ps.
6. Use the Spartan-3A Jitter Calculator (www.xilinx.com/support/documentation/data_sheets/s3a_jitter_calc.zip) to estimate DFS output jitter. Use the Clocking Wizard to determine jitter for a specific design.

TQ144: 144-lead Thin Quad Flat Package

The XC3S100E and the XC3S250E FPGAs are available in the 144-lead thin quad flat package, TQ144. Both devices share a common footprint for this package as shown in Table 137 and Figure 82.

Table 137 lists all the package pins. They are sorted by bank number and then by pin name of the largest device. Pins that form a differential I/O pair appear together in the table. The table also shows the pin number for each pin and the pin type, as defined earlier.

The TQ144 package only supports 20 address output pins in the Byte-wide Peripheral Interface (BPI) configuration mode. In larger packages, there are 24 BPI address outputs.

An electronic version of this package pinout table and footprint diagram is available for download from the Xilinx web site at:

http://www.xilinx.com/support/documentation/data_sheets/s3e_pin.zip

Revision History

The following table shows the revision history for this document.

Date	Version	Revision
03/01/05	1.0	Initial Xilinx release.
03/21/05	1.1	Added XC3S250E in the CP132 package to Table 129. Corrected number of differential I/O pairs on CP132. Added pinout and footprint information for the CP132, FG400, and FG484 packages. Removed IRDY and TRDY pins from the VQ100, TQ144, and PQ208 packages.
11/23/05	2.0	Corrected title of Table 153. Updated differential pair numbering for some pins in Bank 0 of the FG400 package, affecting Table 152 and Figure 87. Pin functionality and ball assignment were not affected. Added Package Thermal Characteristics section. Added package mass values to Table 125.
03/22/06	3.0	Included I/O pins, not just input-only pins under the VREF description in Table 124. Clarified that some global clock inputs are Input-only pins in Table 124. Added information on the XC3S100E in the CP132 package, affecting Table 129, Table 130, Table 133, Table 134, Table 136, and Figure 81. Ball A12 on the XC3S1600E in the FG320 package a full I/O pin, not an Input-only pin. Corrected the I/O counts for the XC3S1600E in the FG320 package, affecting Table 129, Table 150, Table 151, and Figure 86. Corrected pin type for XC3S1600E balls N14 and N15 in Table 148.
05/19/06	3.1	Minor text edits.
11/09/06	3.4	Added package thermal data for the XC3S100E in the CP132 package to Table 130. Corrected pin migration arrows for balls E17 and F4 between the XC3S500E and XC3S1600E in Table 151. Promoted Module 4 to Production status. Synchronized all modules to v3.4.
03/16/07	3.5	Minor formatting changes.
05/29/07	3.6	Corrected ‘Lxx’ to ‘Lxxy’ in Table 124. Noted that some GCLK and VREF pins are on INPUT pins in Table 124 and Table 129. Added link before Table 127 to Material Declaration Data Sheets.
04/18/08	3.7	Added XC3S500E VQG100 package. Added Material Declaration Data Sheet links in Table 127. Updated Thermal Characteristics in Table 130. Updated links.
08/26/09	3.8	Minor typographical updates.
10/29/12	4.0	Added Notice of Disclaimer. This product is not recommended for new designs. Updated the XC3S250E-FT256 in Table 129.
