

Welcome to [E-XFL.COM](https://www.e-xfl.com)

What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "[Embedded - Microcontrollers](#)"

Details

| | |
|----------------------------|---|
| Product Status | Obsolete |
| Core Processor | PIC |
| Core Size | 8-Bit |
| Speed | 33MHz |
| Connectivity | I ² C, SPI, UART/USART |
| Peripherals | Brown-out Detect/Reset, POR, PWM, WDT |
| Number of I/O | 66 |
| Program Memory Size | 16KB (8K x 16) |
| Program Memory Type | OTP |
| EEPROM Size | - |
| RAM Size | 678 x 8 |
| Voltage - Supply (Vcc/Vdd) | 4.5V ~ 5.5V |
| Data Converters | A/D 16x10b |
| Oscillator Type | External |
| Operating Temperature | -40°C ~ 125°C (TA) |
| Mounting Type | Surface Mount |
| Package / Case | 84-LCC (J-Lead) |
| Supplier Device Package | 84-PLCC (29.31x29.31) |

5.0 RESET

The PIC17CXXX differentiates between various kinds of RESET:

- Power-on Reset (POR)
- Brown-out Reset
- $\overline{\text{MCLR}}$ Reset
- WDT Reset

Some registers are not affected in any RESET condition, their status is unknown on POR and unchanged in any other RESET. Most other registers are forced to a "RESET state". The TO and PD bits are set or cleared differently in different RESET situations, as indicated in Table 5-3. These bits, in conjunction with the $\overline{\text{POR}}$ and $\overline{\text{BOR}}$ bits, are used in software to determine the nature of the RESET. See Table 5-4 for a full description of the RESET states of all registers.

When the device enters the "RESET state", the Data Direction registers (DDR) are forced set, which will make the I/O hi-impedance inputs. The RESET state of some peripheral modules may force the I/O to other operations, such as analog inputs or the system bus.

Note: While the device is in a RESET state, the internal phase clock is held in the Q1 state. Any processor mode that allows external execution will force the RE0/ALE pin as a low output and the RE1/OE and RE2/WR pins as high outputs.

A simplified block diagram of the On-Chip Reset Circuit is shown in Figure 5-1.

- Note 1:** SFR file locations 10h - 17h are banked. The lower nibble of the BSR specifies the bank. All unbanked SFRs ignore the Bank Select Register (BSR) bits.
- 2:** General Purpose Registers (GPR) locations 20h - FFh, 120h - 1FFh, 220h - 2FFh, and 320h - 3FFh are banked. The upper nibble of the BSR specifies this bank. All other GPRs ignore the Bank Select Register (BSR) bits.
- 3:** RAM bank 3 is not implemented on the PIC17C752 and the PIC17C762. Reading any unimplemented register reads '0's.
- 4:** Bank 8 is only implemented on the PIC17C76X devices.

PIC17C7XX

7.3 Stack Operation

PIC17C7XX devices have a 16 x 16-bit hardware stack (Figure 7-1). The stack is not part of either the program or data memory space, and the stack pointer is neither readable nor writable. The PC (Program Counter) is “PUSH’d” onto the stack when a `CALL` or `LCALL` instruction is executed, or an interrupt is acknowledged. The stack is “POP’d” in the event of a `RETURN`, `RETLW`, or a `RETFIE` instruction execution. `PCLATH` is not affected by a “PUSH” or a “POP” operation.

The stack operates as a circular buffer, with the stack pointer initialized to '0' after all RESETS. There is a stack available bit (`STKAV`) to allow software to ensure that the stack will not overflow. The `STKAV` bit is set after a device RESET. When the stack pointer equals `Fh`, `STKAV` is cleared. When the stack pointer rolls over from `Fh` to `0h`, the `STKAV` bit will be held clear until a device RESET.

Note 1: There is not a status bit for stack underflow. The `STKAV` bit can be used to detect the underflow which results in the stack pointer being at the Top-of-Stack.

2: There are no instruction mnemonics called `PUSH` or `POP`. These are actions that occur from the execution of the `CALL`, `RETURN`, `RETLW` and `RETFIE` instructions, or the vectoring to an interrupt vector.

3: After a RESET, if a “POP” operation occurs before a “PUSH” operation, the `STKAV` bit will be cleared. This will appear as if the stack is full (underflow has occurred). If a “PUSH” operation occurs next (before another “POP”), the `STKAV` bit will be locked clear. Only a device RESET will cause this bit to set.

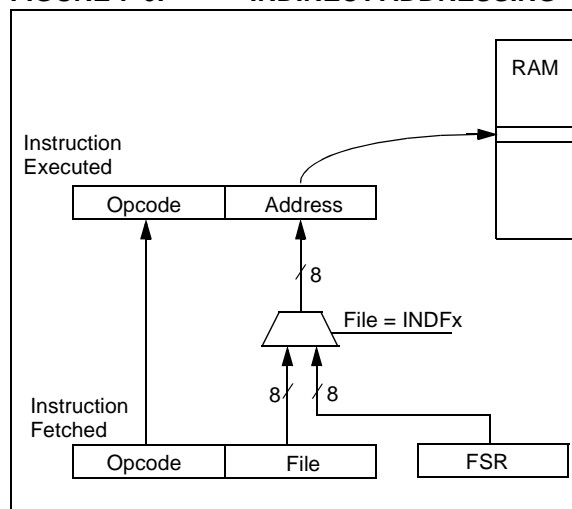

After the device is “PUSH’d” sixteen times (without a “POP”), the seventeenth push overwrites the value from the first push. The eighteenth push overwrites the second push (and so on).

7.4 Indirect Addressing

Indirect addressing is a mode of addressing data memory where the data memory address in the instruction is not fixed. That is, the register that is to be read or written can be modified by the program. This can be useful for data tables in the data memory. Figure 7-6 shows the operation of indirect addressing. This depicts the moving of the value to the data memory address specified by the value of the `FSR` register.

Example 7-1 shows the use of indirect addressing to clear RAM in a minimum number of instructions. A similar concept could be used to move a defined number of bytes (block) of data to the USART transmit register (`TXREG`). The starting address of the block of data to be transmitted could easily be modified by the program.

FIGURE 7-6: INDIRECT ADDRESSING

7.4.1 INDIRECT ADDRESSING REGISTERS

The PIC17C7XX has four registers for indirect addressing. These registers are:

- `INDF0` and `FSR0`
- `INDF1` and `FSR1`

Registers `INDF0` and `INDF1` are not physically implemented. Reading or writing to these registers activates indirect addressing, with the value in the corresponding `FSR` register being the address of the data. The `FSR` is an 8-bit register and allows addressing anywhere in the 256-byte data memory address range. For banked memory, the bank of memory accessed is specified by the value in the `BSR`.

If file `INDF0` (or `INDF1`) itself is read indirectly via an `FSR`, all '0's are read (Zero bit is set). Similarly, if `INDF0` (or `INDF1`) is written to indirectly, the operation will be equivalent to a `NOP`, and the status bits are not affected.

PIC17C7XX

NOTES:

12.0 TIMER0

The Timer0 module consists of a 16-bit timer/counter, TMR0. The high byte is register TMR0H and the low byte is register TMR0L. A software programmable 8-bit prescaler makes Timer0 an effective 24-bit overflow timer. The clock source is software programmable as either the internal instruction clock, or an external clock on the RA1/T0CKI pin. The control bits for this module are in register T0STA (Figure 12-1).

REGISTER 12-1: T0STA REGISTER (ADDRESS: 05h, UNBANKED)

| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | U-0 |
|--------|-------|-------|-------|-------|-------|-------|-------|
| INTEDG | T0SE | T0CS | T0PS3 | T0PS2 | T0PS1 | T0PS0 | — |
| bit 7 | | | | | | | bit 0 |

- bit 7 **INTEDG:** RA0/INT Pin Interrupt Edge Select bit
This bit selects the edge upon which the interrupt is detected.
1 = Rising edge of RA0/INT pin generates interrupt
0 = Falling edge of RA0/INT pin generates interrupt
- bit 6 **T0SE:** Timer0 Clock Input Edge Select bit
This bit selects the edge upon which TMR0 will increment.
When T0CS = 0 (External Clock):
1 = Rising edge of RA1/T0CKI pin increments TMR0 and/or sets the T0CKIF bit
0 = Falling edge of RA1/T0CKI pin increments TMR0 and/or sets the T0CKIF bit
When T0CS = 1 (Internal Clock):
Don't care
- bit 5 **T0CS:** Timer0 Clock Source Select bit
This bit selects the clock source for TMR0.
1 = Internal instruction clock cycle (Tcy)
0 = External clock input on the T0CKI pin
- bit 4-1 **T0PS3:T0PS0:** Timer0 Prescale Selection bits
These bits select the prescale value for TMR0.
- | T0PS3:T0PS0 | Prescale Value |

REGISTER 15-2: SSPCON1: SYNC SERIAL PORT CONTROL REGISTER1 (ADDRESS 11h, BANK 6)

| R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 |
|-------|-------|-------|-------|-------|-------|-------|-------|
| WCOL | SSPOV | SSPEN | CKP | SSPM3 | SSPM2 | SSPM1 | SSPM0 |

bit 7

bit 0

bit 7 **WCOL**: Write Collision Detect bit

Master mode:

1 = A write to the SSPBUF register was attempted while the I²C conditions were not valid for a transmission to be started
0 = No collision

Slave mode:

1 = The SSPBUF register is written while it is still transmitting the previous word (must be cleared in software)
0 = No collision

bit 6 **SSPOV**: Receive Overflow Indicator bit

In SPI mode:

1 = A new byte is received while the SSPBUF register is still holding the previous data. In case of overflow, the data in SSPSR is lost. Overflow can only occur in Slave mode. In Slave mode, the user must read the SSPBUF, even if only transmitting data, to avoid setting overflow. In Master mode, the overflow bit is not set, since each new reception (and transmission) is initiated by writing to the SSPBUF register. (Must be cleared in software.)
0 = No overflow

In I²C mode:

1 = A byte is received while the SSPBUF register is still holding the previous byte. SSPOV is a "don't care" in Transmit mode. (Must be cleared in software.)
0 = No overflow

bit 5 **SSPEN**: Synchronous Serial Port Enable bit

In both modes, when enabled, these pins must be properly configured as input or output.

In SPI mode:

1 = Enables serial port and configures SCK, SDO, SDI and \overline{SS} as the source of the serial port pins
0 = Disables serial port and configures these pins as I/O port pins

In I²C mode:

1 = Enables the serial port and configures the SDA and SCL pins as the source of the serial port pins
0 = Disables serial port and configures these pins as I/O port pins

Note: In SPI mode, these pins must be properly configured as input or output.

bit 4 **CKP**: Clock Polarity Select bit

In SPI mode:

1 = Idle state for clock is a high level
0 = Idle state for clock is a low level

In I²C Slave mode:

SCK release control
1 = Enable clock
0 = Holds clock low (clock stretch). (Used to ensure data setup time.)

In I²C Master mode:

Unused in this mode

bit 3-0 **SSPM3:SSPM0**: Synchronous Serial Port Mode Select bits

0000 = SPI Master mode, clock = Fosc/4
0001 = SPI Master mode, clock = Fosc/16
0010 = SPI Master mode, clock = Fosc/64
0011 = SPI Master mode, clock = TMR2 output/2
0100 = SPI Slave mode, clock = SCK pin, \overline{SS} pin control enabled
0101 = SPI Slave mode, clock = SCK pin, \overline{SS} pin control disabled, \overline{SS} can be used as I/O pin
0110 = I²C Slave mode, 7-bit address
0111 = I²C Slave mode, 10-bit address
1000 = I²C Master mode, clock = Fosc / (4 * (SSPADD+1))
1xx1 = Reserved
1x1x = Reserved

Legend:

R = Readable bit

W = Writable bit

U = Unimplemented bit, read as '0'

- n = Value at POR Reset

'1' = Bit is set

'0' = Bit is cleared

x = Bit is unknown

15.2.2 GENERAL CALL ADDRESS SUPPORT

The addressing procedure for the I²C bus is such that the first byte after the START condition usually determines which device will be the slave addressed by the master. The exception is the general call address, which can address all devices. When this address is used, all devices should, in theory, respond with an acknowledge.

The general call address is one of eight addresses reserved for specific purposes by the I²C protocol. It consists of all 0's with R/W = 0.

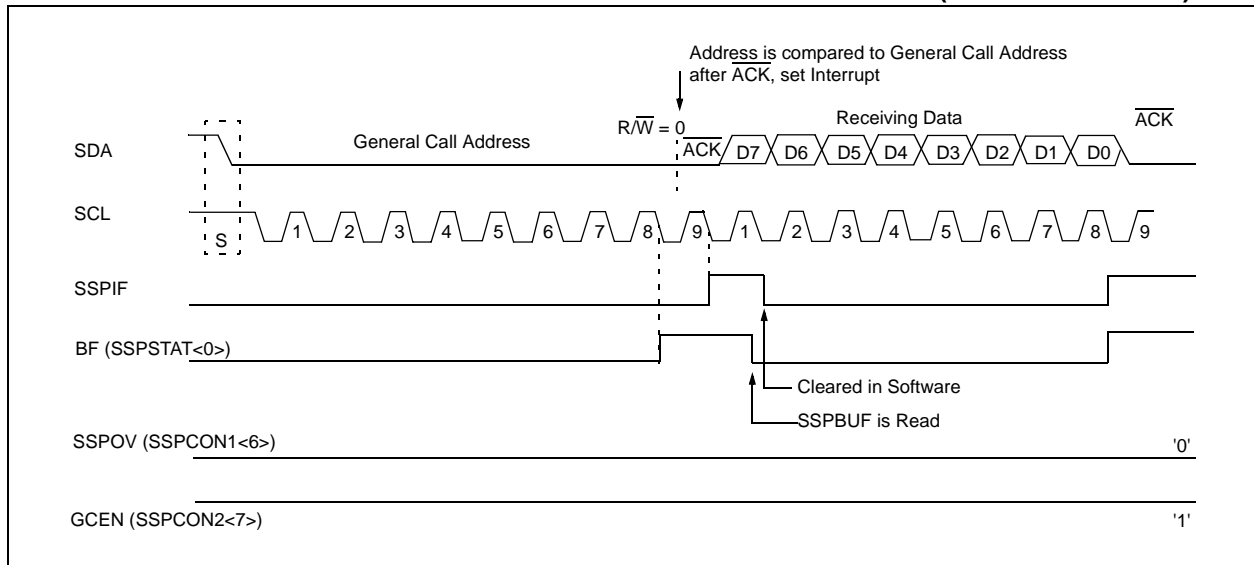

The general call address is recognized when the General Call Enable bit (GCEN) is enabled (SSPCON2<7> is set). Following a START bit detect, 8-bits are shifted into SSPSR and the address is compared against SSPADD and is also compared to the general call address, fixed in hardware.

If the general call address matches, the SSPSR is transferred to the SSPBUF, the BF flag is set (eighth bit) and on the falling edge of the ninth bit ($\overline{\text{ACK}}$ bit), the SSPIF flag is set.

When the interrupt is serviced, the source for the interrupt can be checked by reading the contents of the SSPBUF to determine if the address was device specific, or a general call address.

In 10-bit mode, the SSPADD is required to be updated for the second half of the address to match and the UA bit is set (SSPSTAT<1>). If the general call address is sampled when GCEN is set, while the slave is configured in 10-bit address mode, then the second half of the address is not necessary, the UA bit will not be set and the slave will begin receiving data after the acknowledge (Figure 15-16).

FIGURE 15-16: SLAVE MODE GENERAL CALL ADDRESS SEQUENCE (7 OR 10-BIT MODE)

15.2.6 MULTI-MASTER MODE

In Multi-Master mode, the interrupt generation on the detection of the START and STOP conditions allows the determination of when the bus is free. The STOP (P) and START (S) bits are cleared from a RESET, or when the MSSP module is disabled. Control of the I²C bus may be taken when bit P (SSPSTAT<4>) is set, or the bus is idle, with both the S and P bits clear. When the bus is busy, enabling the SSP interrupt will generate the interrupt when the STOP condition occurs.

In Multi-Master operation, the SDA line must be monitored for arbitration, to see if the signal level is the expected output level. This check is performed in hardware, with the result placed in the BCLIF bit.

The states where arbitration can be lost are:

- Address Transfer
- Data Transfer
- A START Condition
- A Repeated Start Condition
- An Acknowledge Condition

15.2.7 I²C MASTER MODE SUPPORT

Master mode is enabled by setting and clearing the appropriate SSPM bits in SSPCON1 and by setting the SSPEN bit. Once Master mode is enabled, the user has six options.

- Assert a START condition on SDA and SCL.
- Assert a Repeated Start condition on SDA and SCL.
- Write to the SSPBUF register initiating transmission of data/address.
- Generate a STOP condition on SDA and SCL.
- Configure the I²C port to receive data.
- Generate an Acknowledge condition at the end of a received byte of data.

Note: The MSSP Module, when configured in I²C Master mode, does not allow queueing of events. For instance: The user is not allowed to initiate a START condition and immediately write the SSPBUF register to initiate transmission before the START condition is complete. In this case, the SSPBUF will not be written to and the WCOL bit will be set, indicating that a write to the SSPBUF did not occur.

15.2.7.1 I²C Master Mode Operation

The master device generates all of the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a Repeated Start condition. Since the Repeated Start condition is also the beginning of the next serial transfer, the I²C bus will not be released.

In Master Transmitter mode, serial data is output through SDA, while SCL outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7 bits) and the Read/Write (R/W) bit. In this case, the R/W bit will be logic '0'. Serial data is transmitted 8 bits at a time. After each byte is transmitted, an acknowledge bit is received. START and STOP conditions are output to indicate the beginning and the end of a serial transfer.

In Master Receive mode, the first byte transmitted contains the slave address of the transmitting device (7 bits) and the R/W bit. In this case, the R/W bit will be logic '1'. Thus, the first byte transmitted is a 7-bit slave address, followed by a '1' to indicate receive bit. Serial data is received via SDA, while SCL outputs the serial clock. Serial data is received 8 bits at a time. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions indicate the beginning and end of transmission.

The baud rate generator used for SPI mode operation is now used to set the SCL clock frequency for either 100 kHz, 400 kHz, or 1 MHz I²C operation. The baud rate generator reload value is contained in the lower 7 bits of the SSPADD register. The baud rate generator will automatically begin counting on a write to the SSPBUF. Once the given operation is complete (i.e., transmission of the last data bit is followed by ACK), the internal clock will automatically stop counting and the SCL pin will remain in its last state

17.4 Power-down Mode (SLEEP)

The Power-down mode is entered by executing a `SLEEP` instruction. This clears the Watchdog Timer and postscale (if enabled). The \overline{PD} bit is cleared and the \overline{TO} bit is set (in the `CPUSTA` register). In SLEEP mode, the oscillator driver is turned off. The I/O ports maintain their status (driving high, low, or hi-impedance input).

The \overline{MCLR}/VPP pin must be at a logic high level (V_{IHMC}). A WDT time-out RESET does not drive the \overline{MCLR}/VPP pin low.

17.4.1 WAKE-UP FROM SLEEP

The device can wake-up from SLEEP through one of the following events:

- Power-on Reset
- Brown-out Reset
- External RESET input on \overline{MCLR}/VPP pin
- WDT Reset (if WDT was enabled)
- Interrupt from $RA0/INT$ pin, RB port change, $T0CKI$ interrupt, or some peripheral interrupts

The following peripheral interrupts can wake the device from SLEEP:

- Capture interrupts
- USART synchronous slave transmit interrupts
- USART synchronous slave receive interrupts
- A/D conversion complete
- SPI slave transmit/receive complete
- I²C slave receive

Other peripherals cannot generate interrupts since during SLEEP, no on-chip Q clocks are present.

Any RESET event will cause a device RESET. Any interrupt event is considered a continuation of program execution. The \overline{TO} and \overline{PD} bits in the `CPUSTA` register can be used to determine the cause of a device RESET. The \overline{PD} bit, which is set on power-up, is cleared when SLEEP is invoked. The \overline{TO} bit is cleared if WDT time-out occurred (and caused a RESET).

When the `SLEEP` instruction is being executed, the next instruction (`PC + 1`) is pre-fetched. For the device to wake-up through an interrupt event, the corresponding interrupt enable bit must be set (enabled). Wake-up is regardless of the state of the `GLINTD` bit. If the `GLINTD` bit is set (disabled), the device continues execution at the instruction after the `SLEEP` instruction. If the `GLINTD` bit is clear (enabled), the device executes the instruction after the `SLEEP` instruction and then branches to the interrupt vector address. In cases where the execution of the instruction following SLEEP is not desirable, the user should have a `NOP` after the `SLEEP` instruction.

Note: If the global interrupt is disabled (`GLINTD` is set), but any interrupt source has both its interrupt enable bit and the corresponding interrupt flag bit set, the device will immediately wake-up from SLEEP. The \overline{TO} bit is set and the \overline{PD} bit is cleared.

The WDT is cleared when the device wakes from SLEEP, regardless of the source of wake-up.

17.4.1.1 Wake-up Delay

When the oscillator type is configured in XT or LF mode, the Oscillator Start-up Timer (OST) is activated on wake-up. The OST will keep the device in RESET for $1024T_{osc}$. This needs to be taken into account when considering the interrupt response time when coming out of SLEEP.

PIC17C7XX

MOVPF Move p to f

Syntax: `[label] MOVPF p,f`

Operands: $0 \leq f \leq 255$
 $0 \leq p \leq 31$

Operation: $(p) \rightarrow (f)$

Status Affected: Z

Encoding:

| | | | |
|------|------|------|------|
| 010p | pppp | ffff | ffff |
|------|------|------|------|

Description: Move data from data memory location 'p' to data memory location 'f'. Location 'f' can be anywhere in the 256 byte data space (00h to FFh), while 'p' can be 00h to 1Fh.
 Either 'p' or 'f' can be WREG (a useful, special situation).

MOVPF is particularly useful for transferring a peripheral register (e.g. the timer or an I/O port) to a data memory location. Both 'f' and 'p' can be indirectly addressed.

Words: 1

Cycles: 1

Q Cycle Activity:

| Q1 | Q2 | Q3 | Q4 |
|--------|-------------------|--------------|--------------------|
| Decode | Read register 'p' | Process Data | Write register 'f' |

Example: `MOVPF REG1, REG2`

Before Instruction

REG1 = 0x11
 REG2 = 0x33

After Instruction

REG1 = 0x11
 REG2 = 0x11

MOVWF Move WREG to f

Syntax: `[label] MOVWF f`

Operands: $0 \leq f \leq 255$

Operation: $(WREG) \rightarrow (f)$

Status Affected: None

Encoding:

| | | | |
|------|------|------|------|
| 0000 | 0001 | ffff | ffff |
|------|------|------|------|

Description: Move data from WREG to register 'f'. Location 'f' can be anywhere in the 256 byte data space.

Words: 1

Cycles: 1

Q Cycle Activity:

| Q1 | Q2 | Q3 | Q4 |
|--------|-------------------|--------------|--------------------|
| Decode | Read register 'f' | Process Data | Write register 'f' |

Example: `MOVWF REG`

Before Instruction

WREG = 0x4F
 REG = 0xFF

After Instruction

WREG = 0x4F
 REG = 0x4F

| SWAPF | | Swap f | | | | | | |
|-------------------|--|-------------------|--------------|----------------------|------|------|------|------|
| Syntax: | [<i>label</i>] SWAPF f,d | | | | | | | |
| Operands: | $0 \leq f \leq 255$ $d \in [0,1]$ | | | | | | | |
| Operation: | $f<3:0> \rightarrow \text{dest}<7:4>;$ $f<7:4> \rightarrow \text{dest}<3:0>$ | | | | | | | |
| Status Affected: | None | | | | | | | |
| Encoding: | <table border="1"><tr><td>0001</td><td>110d</td><td>ffff</td><td>ffff</td></tr></table> | | | | 0001 | 110d | ffff | ffff |
| 0001 | 110d | ffff | ffff | | | | | |
| Description: | The upper and lower nibbles of register 'f' are exchanged. If 'd' is 0, the result is placed in WREG. If 'd' is 1, the result is placed in register 'f'. | | | | | | | |
| Words: | 1 | | | | | | | |
| Cycles: | 1 | | | | | | | |
| Q Cycle Activity: | | | | | | | | |
| | Q1 | Q2 | Q3 | Q4 | | | | |
| | Decode | Read register 'f' | Process Data | Write to destination | | | | |

Example: SWAPF REG, 0

Before Instruction

REG = 0x53

After Instruction

REG = 0x35

| TABLRD | | Table Read | | | | | | |
|-------------------|--|--|------|--------------|------|-------------------------------|------|------|
| Syntax: | [<i>label</i>] TABLRD t,i,f | | | | | | | |
| Operands: | 0 ≤ f ≤ 255 i ∈ [0,1] t ∈ [0,1] | | | | | | | |
| Operation: | If t = 1, TBLATH → f; If t = 0, TBLATL → f; Prog Mem (TBLPTR) → TBLAT; If i = 1, TBLPTR + 1 → TBLPTR If i = 0, TBLPTR is unchanged | | | | | | | |
| Status Affected: | None | | | | | | | |
| Encoding: | <table><tr><td>1010</td><td>10ti</td><td>ffff</td><td>ffff</td></tr></table> | | | | 1010 | 10ti | ffff | ffff |
| 1010 | 10ti | ffff | ffff | | | | | |
| Description: | <ol style="list-style-type: none">1. A byte of the table latch (TBLAT) is moved to register file 'f'. If t = 1: the high byte is moved; If t = 0: the low byte is moved.2. Then, the contents of the program memory location pointed to by the 16-bit Table Pointer (TBLPTR) are loaded into the 16-bit Table Latch (TBLAT).3. If i = 1: TBLPTR is incremented; If i = 0: TBLPTR is not incremented. | | | | | | | |
| Words: | 1 | | | | | | | |
| Cycles: | 2 (3-cycle if f = PCL) | | | | | | | |
| Q Cycle Activity: | | | | | | | | |
| Q1 | | Q2 | | Q3 | | Q4 | | |
| Decode | | Read register TBLATH or TBLATL | | Process Data | | Write register 'f' | | |
| No operation | | No operation (Table Pointer on Address bus) | | No operation | | No operation (OE goes low) | | |

19.0 DEVELOPMENT SUPPORT

The PIC® microcontrollers are supported with a full range of hardware and software development tools:

- Integrated Development Environment
 - MPLAB® IDE Software
- Assemblers/Compilers/Linkers
 - MPASM™ Assembler
 - MPLAB C17 and MPLAB C18 C Compilers
 - MPLINK™ Object Linker/
MPLIB™ Object Librarian
- Simulators
 - MPLAB SIM Software Simulator
- Emulators
 - MPLAB ICE 2000 In-Circuit Emulator
 - ICEPIC™ In-Circuit Emulator
- In-Circuit Debugger
 - MPLAB ICD for PIC16F87X
- Device Programmers
 - PRO MATE® II Universal Device Programmer
 - PICSTART® Plus Entry-Level Development Programmer
- Low Cost Demonstration Boards
 - PICDEM™ 1 Demonstration Board
 - PICDEM 2 Demonstration Board
 - PICDEM 3 Demonstration Board
 - PICDEM 17 Demonstration Board
 - KEELOQ® Demonstration Board

19.1 MPLAB Integrated Development Environment Software

The MPLAB IDE software brings an ease of software development previously unseen in the 8-bit microcontroller market. The MPLAB IDE is a Windows®-based application that contains:

- An interface to debugging tools
 - simulator
 - programmer (sold separately)
 - emulator (sold separately)
 - in-circuit debugger (sold separately)
- A full-featured editor
- A project manager
- Customizable toolbar and key mapping
- A status bar
- On-line help

The MPLAB IDE allows you to:

- Edit your source files (either assembly or 'C')
- One touch assemble (or compile) and download to PIC MCU emulator and simulator tools (automatically updates all project information)
- Debug using:
 - source files
 - absolute listing file
 - machine code

The ability to use MPLAB IDE with multiple debugging tools allows users to easily switch from the cost-effective simulator to a full-featured emulator with minimal retraining.

19.2 MPASM Assembler

The MPASM assembler is a full-featured universal macro assembler for all PIC MCU's.

The MPASM assembler has a command line interface and a Windows shell. It can be used as a stand-alone application on a Windows 3.x or greater system, or it can be used through MPLAB IDE. The MPASM assembler generates relocatable object files for the MPLINK object linker, Intel® standard HEX files, MAP files to detail memory usage and symbol reference, an absolute LST file that contains source lines and generated machine code, and a COD file for debugging.

The MPASM assembler features include:

- Integration into MPLAB IDE projects.
- User-defined macros to streamline assembly code.
- Conditional assembly for multi-purpose source files.
- Directives that allow complete control over the assembly process.

19.3 MPLAB C17 and MPLAB C18 C Compilers

The MPLAB C17 and MPLAB C18 Code Development Systems are complete ANSI 'C' compilers for Microchip's PIC17CXXX and PIC18CXXX family of microcontrollers, respectively. These compilers provide powerful integration capabilities and ease of use not found with other compilers.

For easier source level debugging, the compilers provide symbol information that is compatible with the MPLAB IDE memory display.

PIC17C7XX

FIGURE 20-15: SPI SLAVE MODE TIMING (CKE = 0)

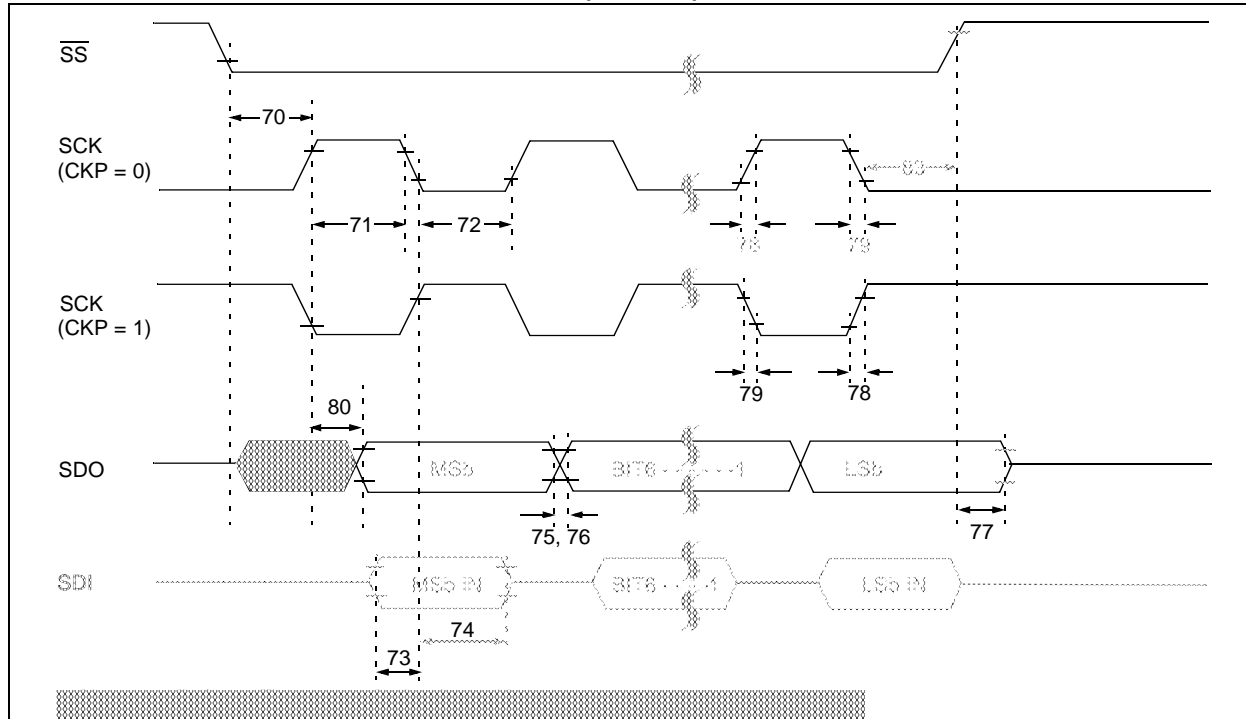

TABLE 20-10: SPI MODE REQUIREMENTS (SLAVE MODE TIMING, CKE = 0)

| Param. No. | Symbol | Characteristic | | Min | Typ† | Max | Units | Conditions |
|------------|--------------------|--|-------------|--------------|------|-----|-------|------------|
| 70 | TssL2scH, TssL2scL | $\overline{SS} \downarrow$ to SCK \downarrow or SCK \uparrow input | | Tcy | — | — | ns | |
| 71 | TscH | SCK input high time (Slave mode) | Continuous | 1.25Tcy + 30 | — | — | ns | |
| 71A | | | Single Byte | 40 | — | — | ns | (Note 1) |
| 72 | TscL | SCK input low time (Slave mode) | Continuous | 1.25Tcy + 30 | — | — | ns | |
| 72A | | | Single Byte | 40 | — | — | ns | (Note 1) |
| 73 | TdiV2scH, TdiV2scL | Setup time of SDI data input to SCK edge | | 100 | — | — | ns | |
| 73A | Tb2b | Last clock edge of Byte1 to the 1st clock edge of Byte2 | | 1.5Tcy + 40 | — | — | ns | (Note 1) |
| 74 | Tsch2diL, TscL2diL | Hold time of SDI data input to SCK edge | | 100 | — | — | ns | |
| 75 | TdoR | SDO data output rise time | | — | 10 | 25 | ns | |
| 76 | TdoF | SDO data output fall time | | — | 10 | 25 | ns | |
| 77 | TssH2doZ | $\overline{SS} \uparrow$ to SDO output hi-impedance | | 10 | — | 50 | ns | |
| 78 | TscR | SCK output rise time (Master mode) | | — | 10 | 25 | ns | |
| 79 | TscF | SCK output fall time (Master mode) | | — | 10 | 25 | ns | |
| 80 | Tsch2doV, TscL2doV | SDO data output valid after SCK edge | | — | — | 50 | ns | |
| 83 | Tsch2ssH, TscL2ssH | $\overline{SS} \uparrow$ after SCK edge | | 1.5Tcy + 40 | — | — | ns | |

† Data in "Typ" column is at 5V, 25°C unless otherwise stated.

Note 1: Specification 73A is only required if specifications 71A and 72A are used.

PIC17C7XX

| Param No. | Sym | Characteristic | | Min | Max | Units | Conditions |
|-----------|------|------------------------|---------------------------|-----|-----|-------|---|
| 110 | Tbuf | Bus free time | 100 kHz mode | 4.7 | — | ms | Time the bus must be free before a new transmission can start |
| | | | 400 kHz mode | 1.3 | — | ms | |
| | | | 1 MHz mode ⁽¹⁾ | 0.5 | — | ms | |
| D102 | Cb | Bus capacitive loading | | — | 400 | pF | |

Note 1: Maximum pin capacitance = 10 pF for all I²C pins.

2: A fast mode (400 KHz) I²C bus device can be used in a standard mode I²C bus system, but the parameter # 107 \geq 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line.

Parameter #102 + #107 = 1000 + 250 = 1250 ns (for 100 kHz mode) before the SCL line is released.
3: C_b is specified to be from 10-400pF. The minimum specifications are characterized with C_b=10pF. The rise time spec (t_r) is characterized with R_p=R_p min. The minimum fall time specification (t_f) is characterized with C_b=10pF, and R_p=R_p max. These are only valid for fast mode operation (V_{DD}=4.5-5.5V) and where the SPM bit (SSPSTAT<7>) =1.)

4: Max specifications for these parameters are valid for falling edge only. Specs are characterized with R_p=R_p min and C_b=400pF for standard mode, 200pF for fast mode, and 10pF for 1MHz mode.

FIGURE 20-19: USART SYNCHRONOUS TRANSMISSION (MASTER/SLAVE) TIMING

TABLE 20-14: USART SYNCHRONOUS TRANSMISSION REQUIREMENTS

| Param No. | Sym | Characteristic | | Min | Typ† | Max | Units | Conditions |
|-----------|----------|---|------------|-----|------|-----|-------|------------|
| 120 | TckH2dtV | <u>SYNC XMIT (MASTER & SLAVE)</u> | | | | | | |
| | | Clock high to data out valid | | | | | | |
| 121 | TckRF | Clock out rise time and fall time (Master mode) | PIC17CXXX | — | — | 50 | ns | |
| | | | PIC17LCXXX | — | — | 75 | ns | |
| | | | PIC17CXXX | — | — | 25 | ns | |
| 122 | TdtRF | Data out rise time and fall time | PIC17CXXX | — | — | 40 | ns | |
| | | | PIC17LCXXX | — | — | 40 | ns | |
| | | | PIC17CXXX | — | — | 25 | ns | |

22.0 PACKAGING INFORMATION

22.1 Package Marking Information

64-Lead TQFP

Example

68-Lead PLCC

Example

80-Lead TQFP

Example

| | | |
|----------------|--------|--|
| Legend: | XX...X | Customer-specific information |
| | Y | Year code (last digit of calendar year) |
| | YY | Year code (last 2 digits of calendar year) |
| | WW | Week code (week of January 1 is week '01') |
| | NNN | Alphanumeric traceability code |
| | (e3) | Pb-free JEDEC designator for Matte Tin (Sn) |
| | * | This package is Pb-free. The Pb-free JEDEC designator (e3) can be found on the outer packaging for this package. |

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.
