Embedded - System On Chip (SoC): The Heart of Modern Embedded Systems

Embedded - System On Chip (SoC) refers to an integrated circuit that consolidates all the essential components of a computer system into a single chip. This includes a microprocessor, memory, and other peripherals, all packed into one compact and efficient package. SoCs are designed to provide a complete computing solution, optimizing both space and power consumption, making them ideal for a wide range of embedded applications.

What are Embedded - System On Chip (SoC)?

System On Chip (SoC) integrates multiple functions of a computer or electronic system onto a single chip. Unlike traditional multi-chip solutions, SoCs combine a central

Notes:

- All voltages are relative to GND.
- For the design of the power distribution system consult *UltraScale Architecture PCB Design Guide* ([UG583](#)).
- V_{CC_PSINTFP_DDR} must be tied to V_{CC_PSINTFP}.
- Includes V_{CCO_PSDDR} of 1.2V, 1.35V, 1.5V at ±5% and 1.1V +0.07V/–0.04V depending upon the tolerances required by specific memory standards.
- Applies to all PS I/O supply banks. Includes V_{CCO_PSIO} of 1.8V, 2.5V, and 3.3V at ±5%.
- If the battery-backed RAM or RTC is not used, connect V_{CC_PSBATT} to GND or V_{CC_PSAUX}. The V_{CC_PSAUX} maximum of 1.89V is acceptable on an unused V_{CC_PSBATT}.
- V_{CCINT_IO} must be connected to V_{CCBRAM}.
- Includes V_{CCO} of 1.0V (HP I/O only), 1.2V, 1.35V, 1.5V, 1.8V, 2.5V (HD I/O only) at ±5%, and 3.3V (HD I/O only) at +3/–5%.
- V_{CCAUX_IO} must be connected to V_{CCAUX}.
- The lower absolute voltage specification always applies.
- A total of 200 mA per bank should not be exceeded.
- Each voltage listed requires filtering as described in *UltraScale Architecture GTH Transceiver User Guide* ([UG576](#)) or *UltraScale Architecture GTY Transceiver User Guide* ([UG578](#)).
- Xilinx recommends measuring the T_j of a device using the system monitor as described in the *UltraScale Architecture System Monitor User Guide* ([UG580](#)). The SYSMON temperature measurement errors (that are described in [Table 69](#) and [Table 124](#)) must be accounted for in your design. For example, when using the PL system monitor with an external reference of 1.25V, when SYSMON reports 97°C, there is a measurement error ±3°C. A reading of 97°C is considered the maximum adjusted T_j (100°C – 3°C = 97°C).
- Devices labeled with the speed/temperature grade of -2LE normally operate under Extended (E) temperature grade specifications with a maximum junction temperature of 100°C. However, E temperature grade devices can operate for a limited time at a junction temperature of 110°C. Timing parameters adhere to the same speed file at 110°C as they do at 100°C, regardless of operating voltage (nominal voltage of 0.85V or a low-voltage of 0.72V). Operation at T_j = 110°C is limited to 1% of the device lifetime and can occur sequentially or at regular intervals as long as the total time does not exceed 1% of the device lifetime.

Power Supply Sequencing

PS Power-On/Off Power Supply Sequencing

The low-power domain (LPD) must operate before the full-power domain (FPD) can function. The low-power and full-power domains can be powered simultaneously. The PS_POR_B input must be asserted to GND during the power-on sequence (see Table 37). The FPD (when used) must be powered before PS_POR_B is released.

To achieve minimum current draw and ensure that the I/Os are 3-stated at power-on, the recommended power-on sequence for the low-power domain (LPD) is listed. The recommended power-off sequence is the reverse of the power-on sequence.

1. $V_{CC_PSINTLP}$
2. V_{CC_PSAUX} , V_{CC_PSADC} , and V_{CC_PSPLL} in any order or simultaneously.
3. V_{CCO_PSIO}

To achieve minimum current draw and ensure that the I/Os are 3-stated at power-on, the recommended power-on sequence for the full-power domain (FPD) is listed. The recommended power-off sequence is the reverse of the power-on sequence.

1. $V_{CC_PSINTFP}$ and $V_{CC_PSINTFP_DDR}$ driven from the same supply source.
2. $V_{PS_MGTRAVCC}$ and $V_{CC_PSDDR_PLL}$ in any order or simultaneously.
3. $V_{PS_MGTRAVTT}$ and V_{CCO_PSDDR} in any order or simultaneously.

PL Power-On/Off Power Supply Sequencing

The recommended power-on sequence is V_{CCINT} , $V_{CCINT_IO}/V_{CCBRAM}/V_{CCINT_VCU}$, V_{CCAUX}/V_{CCAUX_IO} , and V_{CCO} to achieve minimum current draw and ensure that the I/Os are 3-stated at power-on. The recommended power-off sequence is the reverse of the power-on sequence. If V_{CCINT} and V_{CCINT_IO}/V_{CCBRAM} have the same recommended voltage levels, they can be powered by the same supply and ramped simultaneously. V_{CCINT_IO} must be connected to V_{CCBRAM} . If V_{CCAUX}/V_{CCAUX_IO} and V_{CCO} have the same recommended voltage levels, they can be powered by the same supply and ramped simultaneously. V_{CCAUX} and V_{CCAUX_IO} must be connected together. V_{CCADC} and V_{REF} can be powered at any time and have no power-up sequencing requirements.

The recommended power-on sequence to achieve minimum current draw for the GTH or GTY transceivers is V_{CCINT} , $V_{MGTAVCC}$, $V_{MGTAVTT}$ OR $V_{MGTAVCC}$, V_{CCINT} , $V_{MGTAVTT}$. There is no recommended sequencing for $V_{MGTAVCCAUX}$. Both $V_{MGTAVCC}$ and V_{CCINT} can be ramped simultaneously. The recommended power-off sequence is the reverse of the power-on sequence to achieve minimum current draw.

If these recommended sequences are not met, current drawn from $V_{MGTAVTT}$ can be higher than specifications during power-up and power-down.

Programmable Logic (PL) Performance Characteristics

This section provides the performance characteristics of some common functions and designs implemented in Zynq UltraScale+ MPSoC. These values are subject to the same guidelines as the [AC Switching Characteristics, page 22](#). In each table, the I/O bank type is either high performance (HP) or high density (HD).

Notes:

1. LVDS receivers are typically bounded with certain applications to achieve maximum performance. Package skews are not included and should be removed through PCB routing.

Notes:

1. Native mode is supported through the [High-Speed SelectIO Interface Wizard](#) available with the Vivado Design Suite. The performance values assume a source-synchronous interface.
2. PLL settings can restrict the minimum allowable data rate. For example, when using the PLL with CLKOUTPHY_MODE = VCO_HALF the minimum frequency is PLL_F_{VCOMIN}/2.
3. In the SBVA484 package, the maximum data rate is 1260 Mb/s for DDR interfaces and 630 Mb/s for SDR interfaces.
4. LVDS receivers are typically bounded with certain applications to achieve maximum performance. Package skews are not included and should be removed through PCB routing.

Output Delay Measurement Methodology

Output delays are measured with short output traces. Standard termination was used for all testing. The propagation delay of the trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in [Figure 1](#) and [Figure 2](#).

Figure 1: Single-Ended Test Setup

X16640-101316

Figure 2: Differential Test Setup

Parameters V_{REF} , R_{REF} , C_{REF} , and V_{MEAS} fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using this method:

1. Simulate the output driver of choice into the generalized test setup using values from [Table 79](#).
2. Record the time to V_{MEAS} .
3. Simulate the output driver of choice into the actual PCB trace and load using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to V_{MEAS} .
5. Compare the results of [step 2](#) and [step 4](#). The increase or decrease in delay yields the actual propagation delay of the PCB trace.
