

Welcome to [E-XFL.COM](https://www.e-xfl.com)

What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "[Embedded - Microcontrollers](#)"

Details

Product Status	Obsolete
Core Processor	8051
Core Size	8-Bit
Speed	25MHz
Connectivity	SMBus (2-Wire/I ² C), SPI, UART/USART, USB
Peripherals	Brown-out Detect/Reset, POR, PWM, Temp Sensor, WDT
Number of I/O	21
Program Memory Size	16KB (16K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	2.25K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	A/D 13x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	28-VFQFN Exposed Pad
Supplier Device Package	28-MLP (5x5)
Purchase URL	https://www.e-xfl.com/product-detail/silicon-labs/c8051f321

C8051F320/1

1.1. CIP-51™ Microcontroller Core

1.1.1. Fully 8051 Compatible

The C8051F320/1 family utilizes Silicon Labs' proprietary CIP-51 microcontroller core. The CIP-51 is fully compatible with the MCS-51™ instruction set; standard 803x/805x assemblers and compilers can be used to develop software. The CIP-51 core offers all the peripherals included with a standard 8052, including four 16-bit counter/timers, a full-duplex UART with extended baud rate configuration, an enhanced SPI port, 2304 bytes of on-chip RAM, 128 byte Special Function Register (SFR) address space, and 25/21 I/O pins.

1.1.2. Improved Throughput

The CIP-51 employs a pipelined architecture that greatly increases its instruction throughput over the standard 8051 architecture. In a standard 8051, all instructions except for MUL and DIV take 12 or 24 system clock cycles to execute with a maximum system clock of 12-to-24 MHz. By contrast, the CIP-51 core executes 70% of its instructions in one or two system clock cycles, with only four instructions taking more than four system clock cycles.

The CIP-51 has a total of 109 instructions. The table below shows the total number of instructions that require each execution time.

Clocks to Execute	1	2	2/3	3	3/4	4	4/5	5	8
Number of Instructions	26	50	5	14	7	3	1	2	1

With the CIP-51's maximum system clock at 25 MHz, it has a peak throughput of 25 MIPS. Figure 1.3 shows a comparison of peak throughputs for various 8-bit microcontroller cores with their maximum system clocks.

Figure 1.3. Comparison of Peak MCU Execution Speeds

4. PINOUT AND PACKAGE DEFINITIONS

Table 4.1. Pin Definitions for the C8051F320/1

Name	Pin Numbers		Type	Description
	'F320	'F321		
VDD	6	6	Power In	2.7-3.6 V Power Supply Voltage Input.
			Power Out	3.3 V Voltage Regulator Output. See Section 8 .
GND	3	3		Ground.
/RST/	9	9	D I/O	Device Reset. Open-drain output of internal POR or VDD monitor. An external source can initiate a system reset by driving this pin low for at least 15 μ s. See Section 10 .
C2CK			D I/O	Clock signal for the C2 Debug Interface.
P3.0/	10	10	D I/O	Port 3.0. See Section 14 for a complete description.
C2D			D I/O	Bi-directional data signal for the C2 Debug Interface.
REGIN	7	7	Power In	5 V Regulator Input. This pin is the input to the on-chip voltage regulator.
VBUS	8	8	D In	VBUS Sense Input. This pin should be connected to the VBUS signal of a USB network. A 5 V signal on this pin indicates a USB network connection.
D+	4	4	D I/O	USB D+.
D-	5	5	D I/O	USB D-.
P0.0	2	2	D I/O	Port 0.0. See Section 14 for a complete description.
P0.1	1	1	D I/O	Port 0.1. See Section 14 for a complete description.
P0.2/	32	28	D I/O	Port 0.2. See Section 14 for a complete description.
XTAL1			A In	External Clock Input. This pin is the external oscillator return for a crystal or resonator. See Section 13 .
P0.3/	31	27	D I/O	Port 0.3. See Section 14 for a complete description.
XTAL2			A I/O or D In	External Clock Output. This pin is the excitation driver for an external crystal or resonator, or an external clock input for CMOS, capacitor, or RC oscillator configurations. See Section 13 .
P0.4	30	26	D I/O	Port 0.4. See Section 14 for a complete description.
P0.5	29	25	D I/O	Port 0.5. See Section 14 for a complete description.

5. 10-BIT ADC (ADC0)

The ADC0 subsystem for the C8051F320/1 consists of two analog multiplexers (referred to collectively as AMUX0) with 17 total input selections, and a 200 kps, 10-bit successive-approximation-register ADC with integrated track-and-hold and programmable window detector. The AMUX0, data conversion modes, and window detector are all configurable under software control via the Special Function Registers shown in Figure 5.1. ADC0 operates in both Single-ended and Differential modes, and may be configured to measure P1.0-P3.0, the Temperature Sensor output, or VDD with respect to P1.0-P3.0, VREF, or GND. The ADC0 subsystem is enabled only when the AD0EN bit in the ADC0 Control register (ADC0CN) is set to logic 1. The ADC0 subsystem is in low power shutdown when this bit is logic 0.

Bit7: CP1EN: Comparator1 Enable Bit. 0: Comparator1 Disabled. 1: Comparator1 Enabled. Bit6: CP1OUT: Comparator1 Output State Flag. 0: Voltage on CP1+ < CP1-. 1: Voltage on CP1+ > CP1-. Bit5: CP1RIF: Comparator1 Rising-Edge Flag. 0: No Comparator1 Rising Edge has occurred since this flag was last cleared. 1: Comparator1 Rising Edge has occurred. Bit4: CP1FIF: Comparator1 Falling-Edge Flag. 0: No Comparator1 Falling-Edge has occurred since this flag was last cleared. 1: Comparator1 Falling-Edge has occurred. Bits3-2: CP1HYP1-0: Comparator1 Positive Hysteresis Control Bits. 00: Positive Hysteresis Disabled. 01: Positive Hysteresis = 5 mV. 10: Positive Hysteresis = 10 mV. 11: Positive Hysteresis = 20 mV. Bits1-0: CP1HYN1-0: Comparator1 Negative Hysteresis Control Bits. 00: Negative Hysteresis Disabled. 01: Negative Hysteresis = 5 mV. 10: Negative Hysteresis = 10 mV. 11: Negative Hysteresis = 20 mV.								

Figure 7.9. CPT1MD: Comparator1 Mode Selection Register

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	Reset Value
-	-	CP1RIE	CP1FIE	-	-	CP1MD1	CP1MD0	00000010
Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	SFR Address: 0x9C

Bits7-6: UNUSED. Read = 00b, Write = don't care.
 Bit5: CP1RIE: Comparator1 Rising-Edge Interrupt Enable.
 0: Comparator1 rising-edge interrupt disabled.
 1: Comparator1 rising-edge interrupt enabled.
 Bit4: CP1FIE: Comparator1 Falling-Edge Interrupt Enable.
 0: Comparator1 falling-edge interrupt disabled.
 1: Comparator1 falling-edge interrupt enabled.
 Bits1-0: CP1MD1-CP1MD0: Comparator1 Mode Select.
 These bits select the response time for Comparator1.

Mode	CP1MD1	CP1MD0	CP1 Response Time (TYP)
0	0	0	100 ns
1	0	1	175 ns
2	1	0	320 ns
3	1	1	1050 ns

10.1. Power-On Reset

During power-up, the device is held in a reset state and the $\overline{\text{RST}}$ pin is driven low until VDD settles above V_{RST} . A Power-On Reset delay (T_{PORDelay}) occurs before the device is released from reset; this delay is typically less than 0.3 ms. Figure 10.2. plots the power-on and VDD monitor reset timing.

On exit from a power-on reset, the PORSF flag (RSTSRC.1) is set by hardware to logic 1. When PORSF is set, all of the other reset flags in the RSTSRC Register are indeterminate (PORSF is cleared by all other resets). Since all resets cause program execution to begin at the same location (0x0000) software can read the PORSF flag to determine if a power-up was the cause of reset. The content of internal data memory should be assumed to be undefined after a power-on reset. The VDD monitor is enabled following a power-on reset.

Software can force a power-on reset by writing '1' to the PINRSF bit in register RSTSRC.

Figure 10.2. Power-On and VDD Monitor Reset Timing

Notes

Notes

Figure 14.9. P0MDOUT: Port0 Output Mode Register

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	Reset Value
								00000000
Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	SFR Address:
								0xA4

Bits7-0: Output Configuration Bits for P0.7-P0.0 (respectively): ignored if corresponding bit in register P0MDIN is logic 0.
 0: Corresponding P0.n Output is open-drain.
 1: Corresponding P0.n Output is push-pull.

(Note: When SDA and SCL appear on any of the Port I/O, each are open-drain regardless of the value of P0MDOUT).

Figure 14.10. P0SKIP: Port0 Skip Register

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	Reset Value
								00000000
Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	SFR Address:
								0xD4

Bits7-0: P0SKIP[7:0]: Port0 Crossbar Skip Enable Bits.
 These bits select Port pins to be skipped by the Crossbar Decoder. Port pins used as analog inputs (for ADC or Comparator) or used as special functions (VREF input, external oscillator circuit, CNVSTR input) should be skipped by the Crossbar.
 0: Corresponding P0.n pin is not skipped by the Crossbar.
 1: Corresponding P0.n pin is skipped by the Crossbar.

Figure 15.23. EINC5RH: USB0 IN Endpoint Control Low Byte (USB Register)

R/W	R/W	R/W	R	R/W	R/W	R	R	Reset Value
DBIEN	ISO	DIRSEL	-	FCDT	SPLIT	-	-	00000000
Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	USB Address: 0x12
Bit7: DBIEN: IN Endpoint Double-buffer Enable. 0: Double-buffering disabled for the selected IN endpoint. 1: Double-buffering enabled for the selected IN endpoint. Bit6: ISO: Isochronous Transfer Enable. This bit enables/disables isochronous transfers on the current endpoint. 0: Endpoint configured for bulk/interrupt transfers. 1: Endpoint configured for isochronous transfers. Bit5: DIRSEL: Endpoint Direction Select. This bit is valid only when the selected FIFO is not split (SPLIT = '0'). 0: Endpoint direction selected as OUT. 1: Endpoint direction selected as IN. Bit4: Unused. Read = '0'. Write = don't care. Bit3: FCDT: Force Data Toggle. 0: Endpoint data toggle switches only when an ACK is received following a data packet transmission. 1: Endpoint data toggle forced to switch after every data packet is transmitted, regardless of ACK reception. Bit2: SPLIT: FIFO Split Enable. When SPLIT = '1', the selected endpoint FIFO is split. The upper half of the selected FIFO is used by the IN endpoint; the lower half of the selected FIFO is used by the OUT endpoint. Bits1-0: Unused. Read = 00b; Write = don't care.

18.2. SPI0 Master Mode Operation

A SPI master device initiates all data transfers on a SPI bus. SPI0 is placed in master mode by setting the Master Enable flag (MSTEN, SPI0CN.6). Writing a byte of data to the SPI0 data register (SPI0DAT) when in master mode writes to the transmit buffer. If the SPI shift register is empty, the byte in the transmit buffer is moved to the shift register, and a data transfer begins. The SPI0 master immediately shifts out the data serially on the MOSI line while providing the serial clock on SCK. The SPIF (SPI0CN.7) flag is set to logic 1 at the end of the transfer. If interrupts are enabled, an interrupt request is generated when the SPIF flag is set. While the SPI0 master transfers data to a slave on the MOSI line, the addressed SPI slave device simultaneously transfers the contents of its shift register to the SPI master on the MISO line in a full-duplex operation. Therefore, the SPIF flag serves as both a transmit-complete and receive-data-ready flag. The data byte received from the slave is transferred MSB-first into the master's shift register. When a byte is fully shifted into the register, it is moved to the receive buffer where it can be read by the processor by reading SPI0DAT.

When configured as a master, SPI0 can operate in one of three different modes: multi-master mode, 3-wire single-master mode, and 4-wire single-master mode. The default, multi-master mode is active when NSSMD1 (SPI0CN.3) = 0 and NSSMD0 (SPI0CN.2) = 1. In this mode, NSS is an input to the device, and is used to disable the master SPI0 when another master is accessing the bus. When NSS is pulled low in this mode, MSTEN (SPI0CN.6) and SPIEN (SPI0CN.0) are set to 0 to disable the SPI master device, and a Mode Fault is generated (MODF, SPI0CN.5 = 1). Mode Fault will generate an interrupt if enabled. SPI0 must be manually re-enabled in software under these circumstances. In multi-master systems, devices will typically default to being slave devices while they are not acting as the system master device. In multi-master mode, slave devices can be addressed individually (if needed) using general-purpose I/O pins. Figure 18.2 shows a connection diagram between two master devices in multiple-master mode.

3-wire single-master mode is active when NSSMD1 (SPI0CN.3) = 0 and NSSMD0 (SPI0CN.2) = 0. In this mode, NSS is not used, and is not mapped to an external port pin through the crossbar. Any slave devices that must be addressed in this mode should be selected using general-purpose I/O pins. Figure 18.3 shows a connection diagram between a master device in 3-wire master mode and a slave device.

4-wire single-master mode is active when NSSMD1 (SPI0CN.3) = 1. In this mode, NSS is configured as an output pin, and can be used as a slave-select signal for a single SPI device. In this mode, the output value of NSS is controlled (in software) with the bit NSSMD0 (SPI0CN.2). Additional slave devices can be addressed using general-purpose I/O pins. Figure 18.4 shows a connection diagram for a master device in 4-wire master mode and two slave devices.

Figure 18.10. SPI0CKR: SPI0 Clock Rate Register

R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	Reset Value
SCR7	SCR6	SCR5	SCR4	SCR3	SCR2	SCR1	SCR0	00000000
Bit7	Bit6	Bit5	Bit4	Bit3	Bit2	Bit1	Bit0	

SFR Address: 0xA2

Bits 7-0: SCR7-SCR0: SPI0 Clock Rate.

These bits determine the frequency of the SCK output when the SPI0 module is configured for master mode operation. The SCK clock frequency is a divided version of the system clock, and is given in the following equation, where *SYSCLK* is the system clock frequency and *SPI0CKR* is the 8-bit value held in the SPI0CKR register.

$$f_{SCK} = \frac{SYSCLK}{2 \times (SPI0CKR + 1)}$$

for 0 <= SPI0CKR <= 255

Example: If SYSCLK = 2 MHz and SPI0CKR = 0x04,

$$f_{SCK} = \frac{2000000}{2 \times (4 + 1)}$$

$$f_{SCK} = 200kHz$$

Table 18.1. SPI Slave Timing Parameters

PARAMETER	DESCRIPTION	MIN	MAX	UNITS
MASTER MODE TIMING[†] (See Figure 18.12 and Figure 18.13)				
T_{MCKH}	SCK High Time	1*T _{SYSClk}		ns
T_{MCKL}	SCK Low Time	1*T _{SYSClk}		ns
T_{MIS}	MISO Valid to SCK Shift Edge	1*T _{SYSClk} + 20		ns
T_{MIH}	SCK Shift Edge to MISO Change	0		ns
SLAVE MODE TIMING[†] (See Figure 18.14 and Figure 18.15)				
T_{SE}	NSS Falling to First SCK Edge	2*T _{SYSClk}		ns
T_{SD}	Last SCK Edge to NSS Rising	2*T _{SYSClk}		ns
T_{SEZ}	NSS Falling to MISO Valid		4*T _{SYSClk}	ns
T_{SDZ}	NSS Rising to MISO High-Z		4*T _{SYSClk}	ns
T_{CKH}	SCK High Time	5*T _{SYSClk}		ns
T_{CKL}	SCK Low Time	5*T _{SYSClk}		ns
T_{SIS}	MOSI Valid to SCK Sample Edge	2*T _{SYSClk}		ns
T_{SIH}	SCK Sample Edge to MOSI Change	2*T _{SYSClk}		ns
T_{SOH}	SCK Shift Edge to MISO Change		4*T _{SYSClk}	ns
T_{SLH}	Last SCK Edge to MISO Change (CKPHA = 1 ONLY)	6*T _{SYSClk}	8*T _{SYSClk}	ns
[†] T _{SYSClk} is equal to one period of the device system clock (SYSClk).				

When T3SOF = '1', Timer 3 operates in USB Start-of-Frame (SOF) capture mode. When T3SPLIT = '0', Timer 3 counts up and overflows from 0xFFFF to 0x0000. Each time a USB SOF is received, the contents of the Timer 3 registers (TMR3H:TMR3L) are latched into the Timer 3 Reload registers (TMR3RLH:TMR3RLL). A Timer 3 interrupt is generated if enabled. This mode can be used to calibrate the system clock or external oscillator against the known USB host SOF clock.
