What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	MIPS32® M-Class
Core Size	32-Bit Single-Core
Speed	200MHz
Connectivity	CANbus, EBI/EMI, Ethernet, I²C, PMP, SPI, SQI, UART/USART, USB OTG
Peripherals	Brown-out Detect/Reset, DMA, I²S, POR, PWM, WDT
Number of I/O	120
Program Memory Size	512KB (512K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	128K x 8
Voltage - Supply (Vcc/Vdd)	2.1V ~ 3.6V
Data Converters	A/D 48x12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	144-TFBGA
Supplier Device Package	144-TFBGA (7x7)

3.1 Architecture Overview

The MIPS32 M-Class Microprocessor core in PIC32MZ EF family devices contains several logic blocks working together in parallel, providing an efficient high-performance computing engine. The following blocks are included with the core:

- Execution unit
- General Purpose Register (GPR)
- Multiply/Divide Unit (MDU)
- System control coprocessor (CP0)
- Floating Point Unit (FPU)
- Memory Management Unit (MMU)
- Instruction/Data cache controllers
- Power Management
- Instructions and data caches
- microMIPS support
- Enhanced JTAG (EJTAG) controller

3.1.1 EXECUTION UNIT

The processor core execution unit implements a load/store architecture with single-cycle ALU operations (logical, shift, add, subtract) and an autonomous multiply/divide unit. The core contains thirty-two 32-bit General Purpose Registers (GPRs) used for integer operations and address calculation. Seven additional register file shadow sets (containing thirty-two registers) are added to minimize context switching overhead during interrupt/exception processing. The register file consists of two read ports and one write port and is fully bypassed to minimize operation latency in the pipeline.

The execution unit includes:

- 32-bit adder used for calculating the data address
- Address unit for calculating the next instruction address
- Logic for branch determination and branch target address calculation
- Load aligner
- Trap condition comparator
- Bypass multiplexers used to avoid stalls when executing instruction streams where data producing instructions are followed closely by consumers of their results
- Leading Zero/One detect unit for implementing the `CLZ` and `CLO` instructions
- Arithmetic Logic Unit (ALU) for performing arithmetic and bitwise logical operations
- Shifter and store aligner
- DSP ALU and logic block for performing DSP instructions, such as arithmetic/shift/compare operations

3.1.2 MULTIPLY/DIVIDE UNIT (MDU)

The processor core includes a Multiply/Divide Unit (MDU) that contains a separate pipeline for multiply and divide operations, and DSP ASE multiply instructions. This pipeline operates in parallel with the Integer Unit (IU) pipeline and does not stall when the IU pipeline stalls. This allows MDU operations to be partially masked by system stalls and/or other integer unit instructions.

The high-performance MDU consists of a 32x32 booth recoded multiplier, four pairs of result/accumulation registers (HI and LO), a divide state machine, and the necessary multiplexers and control logic. The first number shown ('32' of 32x32) represents the *rs* operand. The second number ('32' of 32x32) represents the *rt* operand.

The MDU supports execution of one multiply or multiply-accumulate operation every clock cycle.

Divide operations are implemented with a simple 1-bit-per-clock iterative algorithm. An early-in detection checks the sign extension of the dividend (*rs*) operand. If *rs* is 8 bits wide, 23 iterations are skipped. For a 16-bit wide *rs*, 15 iterations are skipped and for a 24-bit wide *rs*, 7 iterations are skipped. Any attempt to issue a subsequent `MDU` instruction while a divide is still active causes an IU pipeline stall until the divide operation has completed.

Table 3-1 lists the repeat rate (peak issue rate of cycles until the operation can be reissued) and latency (number of cycles until a result is available) for the processor core multiply and divide instructions. The approximate latency and repeat rates are listed in terms of pipeline clocks.

TABLE 3-1: MIPS32® M-CLASS MICROPROCESSOR CORE HIGH-PERFORMANCE INTEGER MULTIPLY/DIVIDE UNIT LATENCIES AND REPEAT RATES

Pattern Terminate mode:
Any byte matching these bits during a pattern match may be ignored during the pattern match determination when the CHPIGNEN bit is set. If a byte is read that is identical to this data byte, the pattern match logic will treat it as a "don't care" when the pattern matching logic is enabled and the CHPIGEN bit is set.

1 = Allow channel to be chained
0 = Do not allow channel to be chained

Note 1: The chain selection bit takes effect when chaining is enabled (i.e., CHCHN = 1).

2: When the channel is suspended by clearing this bit, the user application should poll the CHBUSY bit (if available on the device variant) to see when the channel is suspended, as it may take some clock cycles to complete a current transaction before the channel is suspended.

bit 31-16 **DCMPHI<15:0>:** Digital Comparator 'x' High Limit Value bits(1,2,3)

These bits store the high limit value, which is used by digital comparator for comparisons with ADC converted data.

bit 15-0 **DCMPLO<15:0>:** Digital Comparator 'x' Low Limit Value bits(1,2,3)

These bits store the low limit value, which is used by digital comparator for comparisons with ADC converted data.

Note 1: Changing theses bits while the Digital Comparator is enabled (ENDCMP = 1) can result in unpredictable behavior.

2: The format of the limit values should match the format of the ADC converted value in terms of sign and fractional settings.

3: For Digital Comparator 0 used in CVD mode, the DCMPHI<15:0> and DCMPLO<15:0> bits must always be specified in signed format, as the CVD output data is differential and is always signed.

2: The ADC module is functional at VBORMIN < VDD < VDDMIN, but with degraded performance. Unless otherwise stated, module functionality is guaranteed, but not characterized.

TABLE A-1: OSCILLATOR CONFIGURATION DIFFERENCES (CONTINUED)

PIC32MX5XX/6XX/7XX Feature	PIC32MZ EF Feature
Crystal/Oscillator Selection for USB	
Any frequency that can be divided down to 4 MHz using UPLLIDIV, including 4, 8, 12, 16, 20, 40, and 48 MHz.	If the USB module is used, the Primary Oscillator is limited to either 12 MHz or 24 MHz. Which frequency is used is selected using the UPLLFSEL (DEVCFG2<30>) bit.
USB PLL Configuration	
On PIC32MX devices, the PLL for the USB requires an input frequency of 4 MHz. **UPLLIDIV<2:0> (DEVCFG2<10:8>)** **111 = 12x divider** **110 = 10x divider** **101 = 6x divider** **100 = 5x divider** **011 = 4x divider** **010 = 3x divider** **010 = 3x divider** **001 = 2x divider** **000 = 1x divider**	On PIC32MZ EF devices, the HS USB PHY requires an input frequency of 12 MHz or 24 MHz. UPLLIDIV has been replaced with UPLLFSEL. **UPLLFSEL (DEVCFG2<30>)** **1 = UPLL input clock is 24 MHz** **0 = UPLL input clock is 12 MHz**
Peripheral Bus Clock Configuration	
On PIC32MX devices, there is one peripheral bus, and the clock for that bus is divided from the SYSCLK using FPBDIV/PBDIV. In addition, the maximum PBCLK frequency is the same as SYSCLK. **FPBDIV<1:0> (DEVCFG1<5:4>)** PBDIV<**1**:0> (**OSCCON<20:19>**) **11 = PBCLK is SYSCLK divided by 8** **10 = PBCLK is SYSCLK divided by 4** **01 = PBCLK is SYSCLK divided by 2** **00 = PBCLK is SYSCLK divided by 1**	On PIC32MZ EF devices, there are eight peripheral buses with their own clocks. FPBDIV is removed, and each PBDIV is in its own register for each PBCLK. The initial PBCLK speed is fixed at reset, and the maximum PBCLK speed is limited to100 MHz for all buses, with the exception of PBCLK7, which is 200 MHz. PBDIV<**6**:0> (**PBxDIV**<**6**:0>) **1111111 = PBCLKx is SYSCLK divided by 128** **1111110 = PBCLKx is SYSCLK divided by 127** • • • **0000011 = PBCLKx is SYSCLK divided by 4** **0000010 = PBCLKx is SYSCLK divided by 3** **0000001 = PBCLKx is SYSCLK divided by 2** **(default value for x < 7)** **0000000 = PBCLKx is SYSCLK divided by 1** **(default value for x ≥ 7)**
CPU Clock Configuration	
On PIC32MX devices, the CPU clock is derived from SYSCLK.	On PIC32MZ EF devices, the CPU clock is derived from PBCLK7.
FRCDIV Default	
On PIC32MX devices, the default value for FRCDIV was to divide the FRC clock by two. FRCDIV<2:0> (OSCCON<26:24>) 111 = FRC divided by 256 110 = FRC divided by 64 101 = FRC divided by 32 100 = FRC divided by 16 011 = FRC divided by 8 010 = FRC divided by 4 001 = FRC divided by 2 **(default)** 000 = FRC divided by 1	On PIC32MZ EF devices, the default has been changed to divide by one. FRCDIV<2:0> (OSCCON<26:24>) 111 = FRC divided by 256 110 = FRC divided by 64 101 = FRC divided by 32 100 = FRC divided by 16 011 = FRC divided by 8 010 = FRC divided by 4 001 = FRC divided by 2 000 = FRC divided by 1 **(default)**
