What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	e200z7
Core Size	32-Bit Tri-Core
Speed	264MHz
Connectivity	EBI/EMI, Ethernet, FlexCANbus, LINbus, SCI, SPI
Peripherals	DMA, LVD, POR, Zipwire
Number of I/O	-
Program Memory Size	8MB (8M x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	512K x 8
Voltage - Supply (Vcc/Vdd)	3V ~ 5.5V
Data Converters	A/D 16b Sigma-Delta, eQADC
Oscillator Type	Internal
Operating Temperature	-40°C ~ 125°C (TA)
Mounting Type	Surface Mount
Package / Case	516-BGA
Supplier Device Package	516-MAPBGA (27x27)

1. I_{DD} measured on an application-specific pattern with all cores enabled at full frequency, T_J = 40°C to 150°C. Flash memory program/erase current on the V_{DD} supply not included.
2. This value is considering the use of the internal core regulator with the simulation of an external transistor with the minimum value of h_{FE} of 60.
3. This bandgap reference is for EQADC calibration and Temperature Sensors.

3.6 I/O pad specifications

The following table describes the different pad types on the chip.

Table 5. I/O pad specification descriptions

Pad type	Description
General-purpose I/O pads	General-purpose I/O and EBI data bus pads with four selectable output slew rate settings; also called SR pads
EBI pads	Provide necessary speed for fast external memory interfaces on the EBI CLKOUT, address, and control signals; also called FC pads
LVDS pads	Low Voltage Differential Signal interface pads
Input-only pads	Low-input-leakage pads that are associated with the ADC channels

NOTE

Each I/O pin on the device supports specific drive configurations. See the signal description table in the device reference manual for the available drive configurations for each I/O pin.

NOTE

Throughout the I/O pad specifications, the symbol V_{DDEx} represents all V_{DDEx} and V_{DDEHx} segments.

3.6.1 Input pad specifications

Table 6 provides input DC electrical characteristics as described in Figure 4.

Table 7. I/O pullup/pulldown DC electrical characteristics

I_{ADV_D}	SDADC supply consumption	Per SDADC enabled	—	—	4.325	mA
I_{ADR_D}	SDADC reference current consumption	Per SDADC enabled	—	—	20	µA

1. For input voltage above the maximum and below the clamp voltage of the input pad, there is no latch-up concern, and the signal will only be “clipped.”
2. VINP is the input voltage applied to the positive terminal of the SDADC
3. VINM is the input voltage applied to the negative terminal of the SDADC
4. Sampling is generated internally $f_{SAMPLING} = f_{ADCD\_M}/2$
5. For Gain = 16, SDADC resolution is 15 bit.
6. Calibration of gain is possible when gain = 1. Offset Calibration should be done with respect to $0.5*V_{RH\_SD}$ for differential mode and single ended mode with negative input = $0.5*V_{RH\_SD}$. Offset Calibration should be done with respect to 0 for single ended mode with negative input = 0. Both Offset and Gain Calibration is guaranteed for +/–5% variation of V_{RH_SD}, +/–10% variation of V_{DDA_SD}, +/–50 C temperature variation.
7. Offset and gain error due to temperature drift can occur in either direction (+/–) for each of the SDADCs on the device.
8. SDADC is functional in the range $3.6\ V < V_{DDA\_SD} < 4.0\ V$: SNR parameter degrades by 3 dB. SDADC is functional in the range $3.0\ V < V_{RH\_SD} < 4.0\ V$: SNR parameter degrades by 9 dB.
9. SNR values guaranteed only if external noise on the ADC input pin is attenuated by the required SNR value in the frequency range of $f_{ADCD\_M} - f_{ADCD\_S}$ to $f_{ADCD\_M} + f_{ADCD\_S}$, where f_{ADCD_M} is the input sampling frequency and f_{ADCD_S} is the output sample frequency. A proper external input filter should be used to remove any interfering signals in this frequency range.
10. Input impedance in differential mode $Z_{IN} = Z_{DIFF}$
11. Input impedance given at f_{ADCD_M} = 16 MHz. Impedance is inversely proportional to SDADC clock frequency. Z_{DIFF} (f_{ADCD_M}) = (16 MHz / f_{ADCD_M}) * Z_{DIFF}, Z_{CM} (f_{ADCD_M}) = (16 MHz / f_{ADCD_M}) * Z_{CM}.
12. Input impedance in single-ended mode $Z_{IN} = (2 * Z_{DIFF} * Z_{CM}) / (Z_{DIFF} + Z_{CM})$
13. V_{INTCM} is the Common Mode input reference voltage for the SDADC. It has a nominal value of $(V_{RH\_SD} - V_{RL\_SD}) / 2$.
14. The ±1% passband ripple specification is equivalent to $20 * \log_{10}(0.99) = 0.087$ dB.
15. Propagation of the information from the pin to the register CDR[CDATA] and the flags SFR[DFEF] and SFR[DFFF] is given by the different modules that must be crossed: delta/sigma filters, high pass filter, FIFO module, and clock domain synchronizers. The time elapsed between data availability at the pin and internal SDADC module registers is given by the following formula, where f_{ADCD_S} is the frequency of the sampling clock, f_{ADCD_M} is the frequency of the modulator, and $f_{FM\_PER\_CLK}$ is the frequency of the peripheral bridge clock feeds to the SDADC module:

    REGISTER LATENCY = $t_{LATENCY} + 0.5/f_{ADCD\_S} + 2\ (\sim+1)/f_{ADCD\_M} + 2(\sim+1)f_{FM\_PER\_CLK}$

    The (~+1) symbol refers to the number of clock cycles uncertainty (from 0 to 1 clock cycle) to be added due to resynchronization of the signal during clock domain crossing.

3.12.2 Flash memory Array Integrity and Margin Read specifications

Table 31. Flash memory Array Integrity and Margin Read specifications

Symbol	Characteristic	Min	Typical	Max[1]	Units [2]
$t_{ai16kseq}$	Array Integrity time for sequential sequence on 16 KB block.	—	—	512 x Tperiod x Nread	—
$t_{ai32kseq}$	Array Integrity time for sequential sequence on 32 KB block.	—	—	1024 x Tperiod x Nread	—
$t_{ai64kseq}$	Array Integrity time for sequential sequence on 64 KB block.	—	—	2048 x Tperiod x Nread	—
tai256kseq	Array Integrity time for sequential sequence on 256 KB block.	—	—	8192 x Tperiod x Nread	—
$t_{mr16kseq}$	Margin Read time for sequential sequence on 16 KB block.	73.81	—	110.7	µs
$t_{mr32kseq}$	Margin Read time for sequential sequence on 32 KB block.	128.43	—	192.6	µs
$t_{mr64kseq}$	Margin Read time for sequential sequence on 64 KB block.	237.65	—	356.5	µs
$t_{mr256kseq}$	Margin Read time for sequential sequence on 256 KB block.	893.01	—	1,339.5	µs

1. Array Integrity times need to be calculated and is dependent on system frequency and number of clocks per read. The equation presented require Tperiod (which is the unit accurate period, thus for 200 MHz, Tperiod would equal 5e-9) and Nread (which is the number of clocks required for read, including pipeline contribution. Thus for a read setup that requires 6 clocks to read with no pipeline, Nread would equal 6. For a read setup that requires 6 clocks to read, and has the address pipeline set to 2, Nread would equal 4 (or 6 - 2).)
2. The units for Array Integrity are determined by the period of the system clock. If unit accurate period is used in the equation, the results of the equation are also unit accurate.

Table 40. eTPU timing[1]

Spec	Characteristic	Symbol	Min	Max	Unit
1	eTPU Input Channel Pulse Width	t_{ICPW}	4	—	t_{CYC_ETPU}[2]
2	eTPU Output Channel Pulse Width	t_{OCPW}	1[3]	—	t_{CYC_ETPU}[2]

1. eTPU timing specified at V_{DD} = 1.08 V to 1.32 V, V_{DDEH} = 3.0 V to 5.5 V, $T_A = T_L$ to T_H, and C_L = 200 pF with SRC = 0b00.
2. For further information on t_{CYC_ETPU}, see Table 3.
3. This specification does not include the rise and fall times. When calculating the minimum eTPU pulse width, include the rise and fall times defined in the slew rate control fields (SRC) of the pad configuration registers (PCR).

3.13.9 DSPI timing with CMOS and LVDS pads

NOTE

The DSPI in TSB mode with LVDS pads can be used to implement the Micro Second Channel (MSC) bus protocol.

DSPI channel frequency support is shown in Table 42. Timing specifications are shown in Table 43, Table 44, Table 45, Table 46, and Table 47.

Table 42. DSPI channel frequency support

DSPI use mode		Max usable frequency (MHz)[1, 2]
CMOS (Master mode)	Full duplex – Classic timing (Table 43)	17
	Full duplex – Modified timing (Table 44)	30
	Output only mode (SCK/SOUT/PCS) (Table 43 and Table 44)	30
	Output only mode TSB mode (SCK/SOUT/PCS) (Table 47)	30
LVDS (Master mode)	Full duplex – Modified timing (Table 45)	30
	Output only mode TSB mode (SCK/SOUT/PCS) (Table 46)	40

1. Maximum usable frequency can be achieved if used with fastest configuration of the highest drive pads.
2. Maximum usable frequency does not take into account external device propagation delay.

1. All output timing is worst case and includes the mismatching of rise and fall times of the output pads.
2. When a characteristic involves two signals, the pad drive and load conditions apply to each signal's pad, unless specified otherwise.
3. All timing values for output signals in this table are measured to 50% of the output voltage.
4. Pad drive is defined as the PCR[SRC] field setting in the SIU. Timing is guaranteed to same drive capabilities for all signals; mixing of pad drives may reduce operating speeds and may cause incorrect operation.
5. N is the number of clock cycles added to time between PCS assertion and SCK assertion and is software programmable using DSPI_CTARx[PSSCK] and DSPI_CTARx[CSSCK]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, N is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
6. t_{SYS} is the period of DSPI_CLKn clock, the input clock to the DSPI module. Maximum frequency is 100 MHz (min t_{SYS} = 10 ns).
7. M is the number of clock cycles added to time between SCK negation and PCS negation and is software programmable using DSPI_CTARx[PASC] and DSPI_CTARx[ASC]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, M is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
8. t_{SDC} is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.
9. PCSx and $\overline{\text{PCSS}}$ using same pad configuration.
10. Input timing assumes an input slew rate of 1 ns (10% – 90%) and uses TTL / Automotive voltage thresholds.
11. P is the number of clock cycles added to delay the DSPI input sample point and is software programmable using DSPI_MCR[SMPL_PT]. The value must be 0, 1 or 2. If the baud rate divide ratio is /2 or /3, this value is automatically set to 1.
12. The 0 pF load condition given in the DSPI AC timing applies to theoretical worst-case hold timing. This guarantees worst-case operation, and additional margin can be achieved in the applications by applying a realistic load.
13. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.

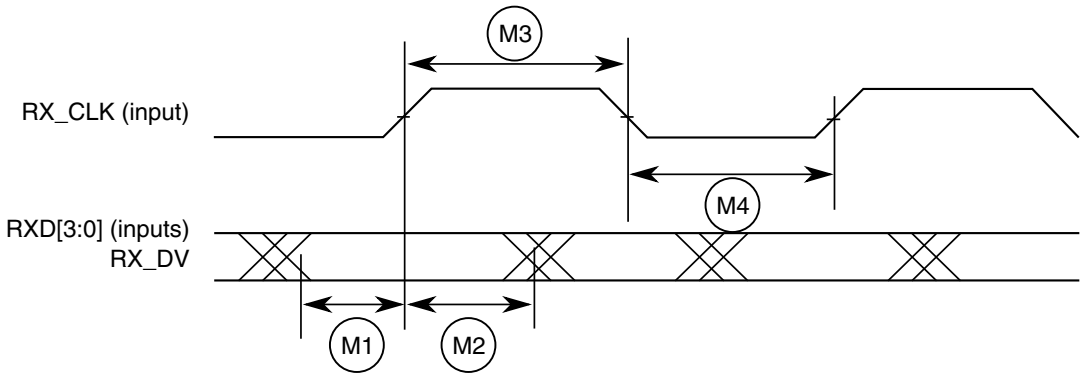

Figure 41. MII receive signal timing diagram

3.13.10.2 MII transmit signal timing (TXD[3:0], TX_EN, and TX_CLK)

The transmitter functions correctly up to a TX_CLK maximum frequency of 25 MHz +1%. There is no minimum frequency requirement. The system clock frequency must be at least equal to or greater than the TX_CLK frequency.

The transmit outputs (TXD[3:0], TX_EN) can be programmed to transition from either the rising or falling edge of TX_CLK, and the timing is the same in either case. This options allows the use of noncompliant MII PHYs.

Refer to the *MPC5777C Microcontroller Reference Manual's* Fast Ethernet Controller (FEC) chapter for details of this option and how to enable it.

Table 49. MII transmit signal timing[1]

Symbol	Characteristic	Value[2]		Unit
		Min	Max	
M5	TX_CLK to TXD[3:0], TX_EN invalid	4.5	—	ns
M6	TX_CLK to TXD[3:0], TX_EN valid	—	25	ns
M7	TX_CLK pulse width high	35%	65%	TX_CLK period
M8	TX_CLK pulse width low	35%	65%	TX_CLK period

1. All timing specifications valid to the pad input levels defined in I/O pad specifications.
2. Output parameters are valid for C_L = 25 pF, where C_L is the external load to the device. The internal package capacitance is accounted for, and does not need to be subtracted from the 25 pF value.

1. Junction temperature is a function of on-chip power dissipation, package thermal resistance, mounting site (board) temperature, ambient temperature, air flow, power dissipation of other components on the board, and board thermal resistance.
2. Per JEDEC JESD51-2 with the single layer board horizontal. Board meets JESD51-9 specification.
3. Per JEDEC JESD51-6 with the board horizontal.
4. Thermal resistance between the die and the printed circuit board per JEDEC JESD51-8. Board temperature is measured on the top surface of the board near the package.
5. Indicates the average thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC-883 Method 1012.1) with the cold plate temperature used for the case temperature.

1. All packaged devices are PPC5777C, rather than MPC5777C or SPC5777C, until product qualifications are complete. The unpackaged device prefix is PCC, rather than SCC, until product qualification is complete.

   Not all configurations are available in the PPC parts.
2. For the operating mode frequency of various blocks on the device, see Table 3.
3. The lowest ambient operating temperature is referenced by T_L; the highest ambient operating temperature is referenced by T_H.
