What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

3.6.3 I/O pad current specifications

The I/O pads are distributed across the I/O supply segments. Each I/O supply segment is associated with a V_{DDEx} supply segment.

Table 11 provides I/O consumption figures.

To ensure device reliability, the average current of the I/O on a single segment should remain below the I_{MAXSEG} value given in Table 1.

To ensure device functionality, the average current of the I/O on a single segment should remain below the I_{MAXSEG} value given in Table 3.

NOTE

The MPC5777C I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel® file attached to the Reference Manual. In the spreadsheet, select the I/O Signal Table tab.

3.7 Oscillator and PLL electrical specifications

The on-chip dual PLL—consisting of the peripheral clock and reference PLL (PLL0) and the frequency-modulated system PLL (PLL1)—generates the system and auxiliary clocks from the main oscillator driver.

5. Below disruptive current conditions, the channel being stressed has conversion values of $3FF for analog inputs greater than V_{RH} and $000 for values less than V_{RL}. Other channels are not affected by non-disruptive conditions.
6. Exceeding limit may cause conversion error on stressed channels and on unstressed channels. Transitions within the limit do not affect device reliability or cause permanent damage.
7. Input must be current limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values using $V_{POSCLAMP} = V_{DDA} + 0.5$ V and $V_{NEGCLAMP} = -0.3$ V, then use the larger of the calculated values.
8. Condition applies to two adjacent pins at injection limits.
9. Performance expected with production silicon.
10. All channels have same 10 kΩ < Rs < 100 kΩ Channel under test has Rs = 10 kΩ, $I_{INJ}=I_{INJMAX},I_{INJMIN}$.
11. The TUE specification is always less than the sum of the INL, DNL, offset, and gain errors due to cancelling errors.
12. TUE does not apply to differential conversions.
13. Variable gain is controlled by setting the PRE_GAIN bits in the ADC_ACR1-8 registers to select a gain factor of ×1, ×2, or ×4. Settings are for differential input only. Tested at ×1 gain. Values for other settings are guaranteed as indicated.
14. Guaranteed 10-bit monotonicity.
15. At $V_{RH\_EQ} - V_{RL\_EQ} = 5.12$ V, one LSB = 1.25 mV.

The SDADC is a 16-bit Sigma-Delta analog-to-digital converter with a 333 Ksps maximum output conversion rate.

1. LVD is released after $t_{VDRELEASE}$ temporization when upper threshold is crossed; LVD is asserted $t_{VDASSERT}$ after detection when lower threshold is crossed.
2. HVD is released after $t_{VDRELEASE}$ temporization when lower threshold is crossed; HVD is asserted $t_{VDASSERT}$ after detection when upper threshold is crossed.
3. POR098_c threshold is an untrimmed value, before the completion of the power-up sequence. All other LVD/HVD thresholds are provided after trimming.
4. LV internal supply levels are measured on device internal supply grid after internal voltage drop.
5. LV external supply levels are measured on the die side of the package bond wire after package voltage drop.
6. V_{DDFLA} range is guaranteed when internal flash memory regulator is used.

3.11.4 Power sequencing requirements

Requirements for power sequencing include the following.

NOTE

In these descriptions, *star route layout* means a track split as close as possible to the power supply source. Each of the split tracks is routed individually to the intended end connection.

1. For both LDO mode and SMPS mode, V_{DDPMC} and V_{DDPWR} must be connected together (shorted) to ensure aligned voltage ramping up/down. In addition:
   - For SMPS mode, a star route layout of the power track is required to minimize mutual noise. If SMPS mode is not used, the star route layout is not required. V_{DDPWR} is the supply pin for the SMPS circuitry.
   - For 3.3 V operation, V_{DDFLA} must also be star routed and shorted to V_{DDPWR} and V_{DDPMC}. This triple connection is required because 3.3 V does not guarantee correct functionality of the internal V_{DDFLA} regulator. Consequently, V_{DDFLA} is supplied externally.
2. V_{DDA_MISC}: IRC operation is required to provide the clock for chip startup.
   - The V_{DDPMC}, V_{DD}, and V_{DDEH1} (reset pin pad segment) supplies are monitored. They hold IRC until all of them reach operational voltage. In other words, V_{DDA_MISC} must reach its specified minimum operating voltage before or at the same time that all of these monitored voltages reach their respective specified minimum voltages.
   - An alternative is to connect the same supply voltage to both V_{DDEH1} and V_{DDA_MISC}. This alternative approach requires a star route layout to minimize mutual noise.
3. Multiple V_{DDEx} supplies can be powered up in any order.

   During any time when V_{DD} is powered up but V_{DDEx} is not yet powered up: pad outputs are unpowered.

   During any time when V_{DDEx} is powered up before all other supplies: all pad output buffers are tristated.
4. Ramp up V_{DDA_EQ} before V_{DD}. Otherwise, a reset might occur.
5. When the device is powering down while using the internal SMPS regulator, V_{DDPMC} and V_{DDPWR} supplies must ramp down through the voltage range from 2.5 V to 1.5 V in less than 1 second. Slower ramp-down times might result in reduced lifetime reliability of the device.

Table 40. eTPU timing[1]

Spec	Characteristic	Symbol	Min	Max	Unit
1	eTPU Input Channel Pulse Width	t_{ICPW}	4	—	t_{CYC_ETPU}[2]
2	eTPU Output Channel Pulse Width	t_{OCPW}	1[3]	—	t_{CYC_ETPU}[2]

2. For further information on t_{CYC_ETPU}, see Table 3.
3. This specification does not include the rise and fall times. When calculating the minimum eTPU pulse width, include the rise and fall times defined in the slew rate control fields (SRC) of the pad configuration registers (PCR).

3.13.9.1.4 DSPI Master Mode – Output Only

Table 46. DSPI LVDS master timing — output only — timed serial bus mode TSB = 1 or ITSB = 1, CPOL = 0 or 1, continuous SCK clock[1, 2]

6	t_{HO}	SOUT data hold time after SCK[7]	LVDS	15 pF to 50 pF differential	–7.0	—	ns

1. All DSPI timing specifications apply to pins when using LVDS pads for SCK and SOUT and CMOS pad for PCS with pad driver strength as defined. Timing may degrade for weaker output drivers.
2. TSB = 1 or ITSB = 1 automatically selects MTFE = 1 and CPHA = 1.
3. When a characteristic involves two signals, the pad drive and load conditions apply to each signal's pad, unless specified otherwise.
4. All timing values for output signals in this table are measured to 50% of the output voltage.
5. Pad drive is defined as the PCR[SRC] field setting in the SIU. Timing is guaranteed to same drive capabilities for all signals; mixing of pad drives may reduce operating speeds and may cause incorrect operation.
6. With TSB mode or Continuous SCK clock mode selected, PCS and SCK are driven by the same edge of DSPI_CLKn. This timing value is due to pad delays and signal propagation delays.
7. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.
