What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Functional Definition

CPU and Memory Subsystem

CPU

The Cortex-M0 CPU in PSoC 4100 is part of the 32-bit MCU subsystem, which is optimized for low power operation with extensive clock gating. It mostly uses 16-bit instructions and executes a subset of the Thumb-2 instruction set. This enables fully compatible binary upward migration of the code to higher performance processors such as the Cortex-M3 and M4, thus enabling upward compatibility. The Cypress implementation includes a hardware multiplier that provides a 32-bit result in one cycle. It includes a nested vectored interrupt controller (NVIC) block with 32 interrupt inputs and also includes a Wakeup Interrupt Controller (WIC), which can wake the processor up from Deep Sleep mode allowing power to be switched off to the main processor when the chip is in Deep Sleep mode. The Cortex-M0 CPU provides a Non-Maskable Interrupt input (NMI), which is made available to the user when it is not in use for system functions requested by the user.

The CPU also includes a debug interface, the serial wire debug (SWD) interface, which is a two-wire form of JTAG; the debug configuration used for PSoC 4100 has four break-point (address) comparators and two watchpoint (data) comparators.

Flash

PSoC 4100 has a flash module with a flash accelerator tightly coupled to the CPU to improve average access times from the flash block. The flash block is designed to deliver 0 wait-state (WS) access time at 24 MHz. Part of the flash module can be used to emulate EEPROM operation if required.

The PSoC 4200 Flash supports the following flash protection modes at the memory subsystem level:

- **Open: No Protection.** Factory default mode in which the product is shipped.
- **Protected: User may change from Open to Protected.** This mode disables Debug interface accesses. The mode can be set back to Open but only after completely erasing the Flash.
- **Kill: User may change from Open to Kill.** This mode disables all Debug accesses. The part cannot be erased externally, thus obviating the possibility of partial erasure by power interruption and potential malfunction and security leaks. This is an irrecvocable mode.

In addition, row-level Read/Write protection is also supported to prevent inadvertent Writes as well as selectively block Reads. Flash Read/Write/Erase operations are always available for internal code using system calls.

SRAM

SRAM memory is retained during Hibernate.

SROM

A supervisory ROM that contains boot and configuration routines is provided.

System Resources

Power System

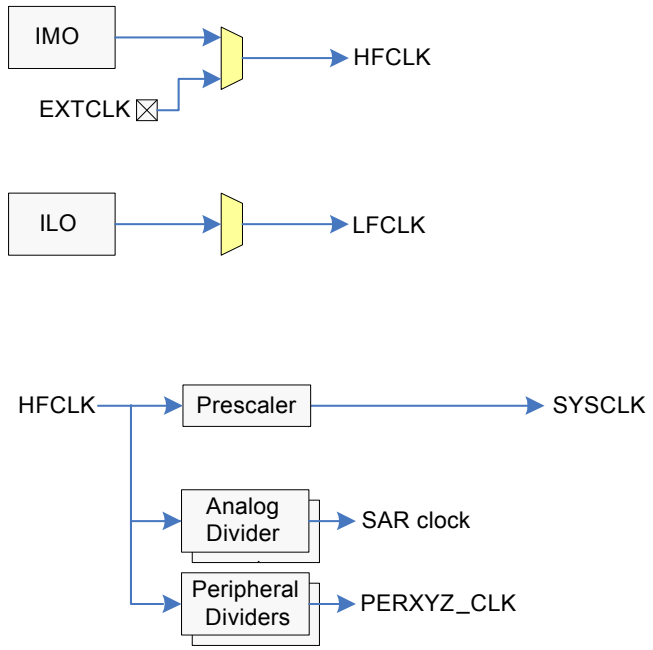
The power system is described in detail in the section Power on page 15. It provides assurance that voltage levels are as required for each respective mode and either delay mode entry (on power-on reset (POR), for example) until voltage levels are as required for proper function or generate resets (brown-out detect (BOD)) or interrupts (low-voltage detect (LVD)). The PSoC 4100 operates with a single external supply over the range of 1.71 V to 5.5 V and has five different power modes, transitions between which are managed by the power system. PSoC 4100 provides Sleep, Deep Sleep, Hibernate, and Stop low-power modes.

Clock System

The PSoC 4100 clock system is responsible for providing clocks to all subsystems that require clocks and for switching between different clock sources without glitching. In addition, the clock system ensures that no metastable conditions occur.

The clock system for PSoC 4100 consists of the internal main oscillator (IMO) and the internal low-power oscillator (ILO) and provision for an external clock.

Figure 3. PSoC 4100 MCU Clocking Architecture



The HFCLK signal can be divided down (see PSoC 4100 MCU Clocking Architecture) to generate synchronous clocks for the analog and digital peripherals. There are a total of 12 clock dividers for PSoC 4100, each with 16-bit divide capability. The analog clock leads the digital clocks to allow analog events to occur before digital clock-related noise is generated. The 16-bit capability allows a lot of flexibility in generating fine-grained frequency values and is fully supported in PSoC Creator.

The following is the pin-list for the PSoC 4100 (35-WLCSP).

Note It is good practice to check the datasheets for your bypass capacitors, specifically the working voltage and the DC bias specifications. With some capacitors, the actual capacitance can decrease considerably when the DC bias (V_{DDA}, V_{DDD}, or V_{CCD}) is a significant percentage of the rated working voltage. V_{DDA} must be equal to or higher than the V_{DDD} supply when powering up.

Regulated External Supply

In this mode, the PSoC 4100 is powered by an external power supply that must be within the range of 1.71 V to 1.89 V (1.8 ±5%); note that this range needs to include power supply ripple too. In this mode, VCCD, VDDA, and VDDD pins are all shorted together and bypassed. The internal regulator is disabled in firmware.
