What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

4.5 Exceptions and Interrupts

In the AVR32 architecture, events are used as a common term for exceptions and interrupts. AVR32UC incorporates a powerful event handling scheme. The different event sources, like Illegal Op-code and interrupt requests, have different priority levels, ensuring a well-defined behavior when multiple events are received simultaneously. Additionally, pending events of a higher priority class may preempt handling of ongoing events of a lower priority class.

When an event occurs, the execution of the instruction stream is halted, and execution is passed to an event handler at an address specified in Table 4-4 on page 38. Most of the handlers are placed sequentially in the code space starting at the address specified by EVBA, with four bytes between each handler. This gives ample space for a jump instruction to be placed there, jumping to the event routine itself. A few critical handlers have larger spacing between them, allowing the entire event routine to be placed directly at the address specified by the EVBA-relative offset generated by hardware. All interrupt sources have autovectored interrupt service routine (ISR) addresses. This allows the interrupt controller to directly specify the ISR address as an address

5.2 Physical Memory Map

The system bus is implemented as a bus matrix. All system bus addresses are fixed, and they are never remapped in any way, not even in boot. Note that AVR32UC CPU uses unsegmented translation, as described in the AVR32 Architecture Manual. The 32-bit physical address space is mapped as follows:

7.9 Timing Characteristics

7.9.1 Startup, Reset, and Wake-up Timing

The startup, reset, and wake-up timings are calculated using the following formula:

$$t = t_{CONST} + N_{CPU} \times t_{CPU}$$

Where t_{CONST} and N_{CPU} are found in Table 7-44. t_{CONST} is the delay relative to RCSYS, t_{CPU} is the period of the CPU clock. If another clock source than RCSYS is selected as CPU clock the startup time of the oscillator, $t_{OSCSTART}$, must be added to the wake-up time in the stop, deepstop, and static sleep modes. Please refer to the source for the CPU clock in the "Oscillator Characteristics" on page 57 for more details about oscillator startup times.

Table 7-44. Maximum Reset and Wake-up Timing

Parameter		Measuring	Max t_{CONST} (in µs)	Max N_{CPU}
Startup time from power-up, using regulator		VDDIN_5 rising (10 mV/ms) Time from V_{VDDIN_5}=0 to the first instruction entering the decode stage of CPU. VDDCORE is supplied by the internal regulator.	2600	0
Startup time from reset release		Time from releasing a reset source (except POR, BOD18, and BOD33) to the first instruction entering the decode stage of CPU.	1240	0
Wake-up	Idle	From wake-up event to the first instruction entering the decode stage of the CPU.	0	19
	Frozen		268	209
	Standby		268	209
	Stop		268+ $t_{OSCSTART}$	212
	Deepstop		268+ $t_{OSCSTART}$	212
	Static		268+ $t_{OSCSTART}$	212

Maximum SPI Frequency, Master Output

The maximum SPI master output frequency is given by the following formula:

$$f_{SPCKMAX} = MIN(f_{PINMAX}, \frac{1}{SPIn}, \frac{f_{CLKSPI} \times 2}{9})$$

Where $SPIn$ is the MOSI delay, USPI2 or USPI5 depending on CPOL and NCPHA. f_{PINMAX} is the maximum frequency of the SPI pins. Please refer to the I/O Pin Characteristics section for the maximum frequency of the pins. f_{CLKSPI} is the maximum frequency of the CLK_SPI. Where $SPIn$ is the MISO setup and hold time, USPI0 + USPI1 or USPI3 + USPI4 depending on CPOL and NCPHA. T_{VALID} is the SPI slave response time. Please refer to the SPI slave datasheet for T_{VALID} . f_{CLKSPI} is the maximum frequency of the CLK_SPI. Refer to the SPI chapter for a description of this clock.

The maximum SPI slave output frequency is given by the following formula:

$$f_{SPCKMAX} = MIN(\frac{f_{CLKSPI} \times 2}{9}, f_{PINMAX}, \frac{1}{SPIn + t_{SETUP}})$$

Where $SPIn$ is the MISO delay, USPI6 or USPI9 depending on CPOL and NCPHA. T_{SETUP} is the SPI master setup time. 10. Errata

10.1 rev E

10.1.1 ADCIFA

1 **ADCREFP/ADCREFN can not be selected as an external ADC reference by setting the ADCIFA.CFG.EXREF bit to one**
Fix/Workaround
A voltage reference can be applied on ADCREFP/ADCREFN pins if the ADCIFA.CFG.EXREF bit is set to zero, the ADCIFA.CFG.RS bit is set to zero and the voltage reference applied on ADCREFP/ADCREFN pins is higher than the internal 1V reference.

10.1.2 AST

1 **AST wake signal is released one AST clock cycle after the BUSY bit is cleared**
After writing to the Status Clear Register (SCR) the wake signal is released one AST clock cycle after the BUSY bit in the Status Register (SR.BUSY) is cleared. If entering sleep mode directly after the BUSY bit is cleared the part will wake up immediately.
Fix/Workaround
Read the Wake Enable Register (WER) and write this value back to the same register. Wait for BUSY to clear before entering sleep mode.

10.1.3 aWire

1 **aWire MEMORY_SPEED_REQUEST command does not return correct CV**
The aWire MEMORY_SPEED_REQUEST command does not return a CV corresponding to the formula in the aWire Debug Interface chapter.
Fix/Workaround
Issue a dummy read to address 0x100000000 before issuing the MEMORY_SPEED_REQUEST command and use this formula instead:

$$f_{sab} = \frac{7 f_{aw}}{CV - 3}$$

10.1.4 Power Manager

1 **TWIS may not wake the device from sleep mode**
If the CPU is put to a sleep mode (except Idle and Frozen) directly after a TWI Start condition, the CPU may not wake upon a TWIS address match. The request is NACKed.
Fix/Workaround
When using the TWI address match to wake the device from sleep, do not switch to sleep modes deeper than Frozen. Another solution is to enable asynchronous EIC wake on the TWIS clock (TWCK) or TWIS data (TWD) pins, in order to wake the system up on bus events.

10.2.10 TWIS

1. **Clearing the NAK bit before the BTF bit is set locks up the TWI bus**
When the TWIS is in transmit mode, clearing the NAK Received (NAK) bit of the Status Register (SR) before the end of the Acknowledge/Not Acknowledge cycle will cause the TWIS to attempt to continue transmitting data, thus locking up the bus.
Fix/Workaround
Clear SR.NAK only after the Byte Transfer Finished (BTF) bit of the same register has been set.

2. **TWIS stretch on Address match error**
When the TWIS stretches TWCK due to a slave address match, it also holds TWD low for the same duration if it is to be receiving data. When TWIS releases TWCK, it releases TWD at the same time. This can cause a TWI timing violation.
Fix/Workaround
None.

3. **TWALM forced to GND**
The TWALM pin is forced to GND when the alternate function is selected and the TWIS module is enabled.
Fix/Workaround
None.

10.2.11 USBC

1. **UPINRQx.INRQ field is limited to 8-bits**
In Host mode, when using the UPINRQx.INRQ feature together with the multi-packet mode to launch a finite number of packet among multi-packet, the multi-packet size (located in the descriptor table) is limited to the UPINRQx.INRQ value multiply by the pipe size.
Fix/Workaround
UPINRQx.INRQ value shall be less than the number of configured multi-packet.

2. **In USB host mode, downstream resume feature does not work (UHCON.RESUME=1).**
Fix/Workaround
None.

3. **In host mode, the disconnection during OUT transition is not supported**
In USB host mode, a pipe can not work if the previous USB device disconnection has occurred during a USB transfer.
Fix/Workaround
Reset the USBC (USBCON.USB=0 and =1) after a device disconnection (UHINT.DDISCI).

4. **In USB host mode, entering suspend mode can fail**
In USB host mode, entering suspend mode can fail when UHCON.SOFE=0 is done just after a SOF reception (UHINT.HSOFI).
Fix/Workaround
Check that UHNUM.FLENHIGH is below 185 in Full speed and below 21 in Low speed before clearing UHCON.SOFE.

5. **In USB host mode, entering suspend mode for low speed device can fail when the USB freeze (USBCON.FRZCLK=1) is done just after UHCON.SOFE=0.**
Fix/Workaround
When entering suspend mode (UHCON.SOFE is cleared), check that USBFSM.DRDSTATE is not equal to three before freezing the clock (USBCON.FRZCLK=1).
