Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

1. Optional signals.

2. For dual port EBR primitives a trailing ‘A’ or ‘B’ in the signal name specifies the EBR port A or port B respectively.
3. For FIFO RAM mode primitive, a trailing ‘R’ or ‘W’ in the signal name specifies the FIFO read port or write port respectively.
4. For FIFO RAM mode primitive FULLI has the same function as CSW(2) and EMPTYI has the same function as CSR(2).
5. In FIFO mode, CLKW is the write port clock, CSW is the write port chip select, CLKR is the read port clock, CSR is the read port chip select, ORE is the output read enable.

Programmable I/O Cells (PIC)

The programmable logic associated with an I/O is called a PIO. The individual PIO are connected to their respective sysIO buffers and pads. On the MachXO2 devices, the PIO cells are assembled into groups of four PIO cells called a Programmable I/O Cell or PIC. The PICs are placed on all four sides of the device.

On all the MachXO2 devices, two adjacent PIOs can be combined to provide a complementary output driver pair.

The MachXO2-640U, MachXO2-1200/U and higher density devices contain enhanced I/O capability. All PIO pairs on these larger devices can implement differential receivers. Half of the PIO pairs on the top edge of these devices can be configured as true LVDS transmit pairs. The PIO pairs on the bottom edge of these higher density devices have on-chip differential termination and also provide PCI support.

PIO

The PIO contains three blocks: an input register block, output register block and tri-state register block. These blocks contain registers for operating in a variety of modes along with the necessary clock and selection logic.

Table 2-8. PIO Signal List

Pin Name	I/O Type	Description
CE	Input	Clock Enable
D	Input	Pin input from sysIO buffer.
INDD	Output	Register bypassed input.
INCK	Output	Clock input
Q0	Output	DDR positive edge input
Q1	Output	Registered input/DDR negative edge input
D0	Input	Output signal from the core (SDR and DDR)
D1	Input	Output signal from the core (DDR)
TD	Input	Tri-state signal from the core
Q	Output	Data output signals to sysIO Buffer
TQ	Output	Tri-state output signals to sysIO Buffer
DQSR90 ¹	Input	DQS shift 90-degree read clock
DQSW90 ¹	Input	DQS shift 90-degree write clock
DDRCLKPOL ¹	Input	DDR input register polarity control signal from DQS
SCLK	Input	System clock for input and output/tri-state blocks.
RST	Input	Local set reset signal

1. Available in PIO on right edge only.

Input Register Block

The input register blocks for the PIOs on all edges contain delay elements and registers that can be used to condition high-speed interface signals before they are passed to the device core. In addition to this functionality, the input register blocks for the PIOs on the right edge include built-in logic to interface to DDR memory.

Figure 2-12 shows the input register block for the PIOs located on the left, top and bottom edges. Figure 2-13 shows the input register block for the PIOs on the right edge.

Left, Top, Bottom Edges

Input signals are fed from the sysIO buffer to the input register block (as signal D). If desired, the input signal can bypass the register and delay elements and be used directly as a combinatorial signal (INDD), and a clock (INCK). If an input delay is desired, users can select a fixed delay. I/Os on the bottom edge also have a dynamic delay, DEL[4:0]. The delay, if selected, reduces input register hold time requirements when using a global clock. The input block allows two modes of operation. In single data rate (SDR) the data is registered with the system clock (SCLK) by one of the registers in the single data rate sync register block. In Generic DDR mode, two registers are used to sample the data on the positive and negative edges of the system clock (SCLK) signal, creating two data streams.

Figure 2-21. I²C Core Block Diagram

Table 2-15 describes the signals interfacing with the I²C cores.

Table 2-15. I²C Core Signal Description

Signal Name	I/O	Description
i2c_scl	Bi-directional	Bi-directional clock line of the I ² C core. The signal is an output if the I ² C core is in master mode. The signal is an input if the I ² C core is in slave mode. MUST be routed directly to the pre-assigned I/O of the chip. Refer to the Pinout Information section of this document for detailed pad and pin locations of I ² C ports in each MachXO2 device.
i2c_sda	Bi-directional	Bi-directional data line of the I ² C core. The signal is an output when data is transmitted from the I ² C core. The signal is an input when data is received into the I ² C core. MUST be routed directly to the pre-assigned I/O of the chip. Refer to the Pinout Information section of this document for detailed pad and pin locations of I ² C ports in each MachXO2 device.
i2c_irqo	Output	Interrupt request output signal of the I ² C core. The intended usage of this signal is for it to be connected to the WISHBONE master controller (i.e. a microcontroller or state machine) and request an interrupt when a specific condition is met. These conditions are described with the I ² C register definitions.
cfg_wake	Output	Wake-up signal – To be connected only to the power module of the MachXO2 device. The signal is enabled only if the “Wakeup Enable” feature has been set within the EFB GUI, I ² C Tab.
cfg_stby	Output	Stand-by signal – To be connected only to the power module of the MachXO2 device. The signal is enabled only if the “Wakeup Enable” feature has been set within the EFB GUI, I ² C Tab.

Hardened SPI IP Core

Every MachXO2 device has a hard SPI IP core that can be configured as a SPI master or slave. When the IP core is configured as a master it will be able to control other SPI enabled chips connected to the SPI bus. When the core is configured as the slave, the device will be able to interface to an external SPI master. The SPI IP core on MachXO2 devices supports the following functions:

- Configurable Master and Slave modes
- Full-Duplex data transfer
- Mode fault error flag with CPU interrupt capability
- Double-buffered data register
- Serial clock with programmable polarity and phase
- LSB First or MSB First Data Transfer
- Interface to custom logic through 8-bit WISHBONE interface

1. Input or I/O leakage current is measured with the pin configured as an input or as an I/O with the output driver tri-stated. It is not measured with the output driver active. Bus maintenance circuits are disabled.
2. T_A 25 °C, $f = 1.0$ MHz.
3. Please refer to V_{IL} and V_{IH} in the sysIO Single-Ended DC Electrical Characteristics table of this document.
4. When V_{IH} is higher than V_{CCIO} , a transient current typically of 30 ns in duration or less with a peak current of 6 mA can occur on the high-to-low transition. For true LVDS output pins in MachXO2-640U, MachXO2-1200/U and larger devices, V_{IH} must be less than or equal to V_{CCIO} .
5. With bus keeper circuit turned on. For more details, refer to TN1202, [MachXO2 sysIO Usage Guide](#).

LVDS Emulation

MachXO2 devices can support LVDS outputs via emulation (LVDS25E). The output is emulated using complementary LVCMS outputs in conjunction with resistors across the driver outputs on all devices. The scheme shown in Figure 3-1 is one possible solution for LVDS standard implementation. Resistor values in Figure 3-1 are industry standard values for 1% resistors.

RSDS

The MachXO2 family supports the differential RSDS standard. The output standard is emulated using complementary LVCMS outputs in conjunction with resistors across the driver outputs on all the devices. The RSDS input standard is supported by the LVDS differential input buffer. The scheme shown in Figure 3-4 is one possible solution for RSDS standard implementation. Use LVDS25E mode with suggested resistors for RSDS operation. Resistor values in Figure 3-4 are industry standard values for 1% resistors.

1. This part number has a tape and reel quantity of 5,000 units with a minimum order quantity of 10,000 units. Order quantities must be in increments of 5,000 units. For example, a 10,000 unit order will be shipped in two reels with one reel containing 5,000 units and the other reel with less than 5,000 units (depending on test yields). Unserviced backlog will be canceled.
2. This part number has a tape and reel quantity of 1,000 units with a minimum order quantity of 1,000. Order quantities must be in increments of 1,000 units. For example, a 5,000 unit order will be shipped as 5 reels of 1000 units each.
3. This part number has a tape and reel quantity of 50 units with a minimum order quantity of 50. Order quantities must be in increments of 50 units. For example, a 1,000 unit order will be shipped as 20 reels of 50 units each.

1. Specifications for the “LCMxo2-1200HC-speed package IR1” are the same as the “LCMxo2-1200ZE-speed package I” devices respectively, except as specified in the [R1 Device Specifications](#) section of this data sheet.

R1 Device Specifications

The LCMXO2-1200ZE/HC “R1” devices have the same specifications as their Standard (non-R1) counterparts except as listed below. For more details on the R1 to Standard migration refer to AN8086, [Designing for Migration from MachXO2-1200-R1 to Standard Non-R1 Devices](#).

- The User Flash Memory (UFM) cannot be programmed through the internal WISHBONE interface. It can still be programmed through the JTAG/SPI/I²C ports.
- The on-chip differential input termination resistor value is higher than intended. It is approximately 200Ω as opposed to the intended 100Ω. It is recommended to use external termination resistors for differential inputs. The on-chip termination resistors can be disabled through Lattice design software.
- Soft Error Detection logic may not produce the correct result when it is run for the first time after configuration. To use this feature, discard the result from the first operation. Subsequent operations will produce the correct result.
- Under certain conditions, I_{ILH} exceeds data sheet specifications. The following table provides more details:

Condition	Clamp	Pad Rising I _{ILH} Max.	Pad Falling I _{ILH} Min.	Steady State Pad High I _{ILH}	Steady State Pad Low I _{ILH}
VPAD > VCCIO	OFF	1 mA	-1 mA	1 mA	10 µA
VPAD = VCCIO	ON	10 µA	-10 µA	10 µA	10 µA
VPAD = VCCIO	OFF	1 mA	-1 mA	1 mA	10 µA
VPAD < VCCIO	OFF	10 µA	-10 µA	10 µA	10 µA

- The user SPI interface does not operate correctly in some situations. During master read access and slave write access, the last byte received does not generate the RRDY interrupt.
- In GDDRX2, GDDRX4 and GDDR71 modes, ECLKSYNC may have a glitch in the output under certain conditions, leading to possible loss of synchronization.
- When using the hard I²C IP core, the I²C status registers I₂C_1_SR and I₂C_2_SR may not update correctly.
- PLL Lock signal will glitch high when coming out of standby. This glitch lasts for about 10 µsec before returning low.
- Dual boot only available on HC devices, requires tying VCC and VCCIO2 to the same 3.3 V or 2.5 V supply.
