Understanding [Embedded - Microprocessors](#)

Embedded microprocessors are specialized computing chips designed to perform specific tasks within an embedded system. Unlike general-purpose microprocessors found in personal computers, embedded microprocessors are tailored for dedicated functions within larger systems, offering optimized performance, efficiency, and reliability. These microprocessors are integral to the operation of countless electronic devices, providing the computational power necessary for controlling processes, handling data, and managing communications.

Applications of [Embedded - Microprocessors](#)

Embedded microprocessors are utilized across a broad spectrum of applications, making them indispensable in

Features

The MPC866/859 is comprised of three modules that each use a 32-bit internal bus: MPC8xx core, system integration unit (SIU), and communication processor module (CPM). The MPC866P block diagram is shown in [Figure 1](#). The MPC859P/859T/859DSL block diagram is shown in [Figure 2](#).

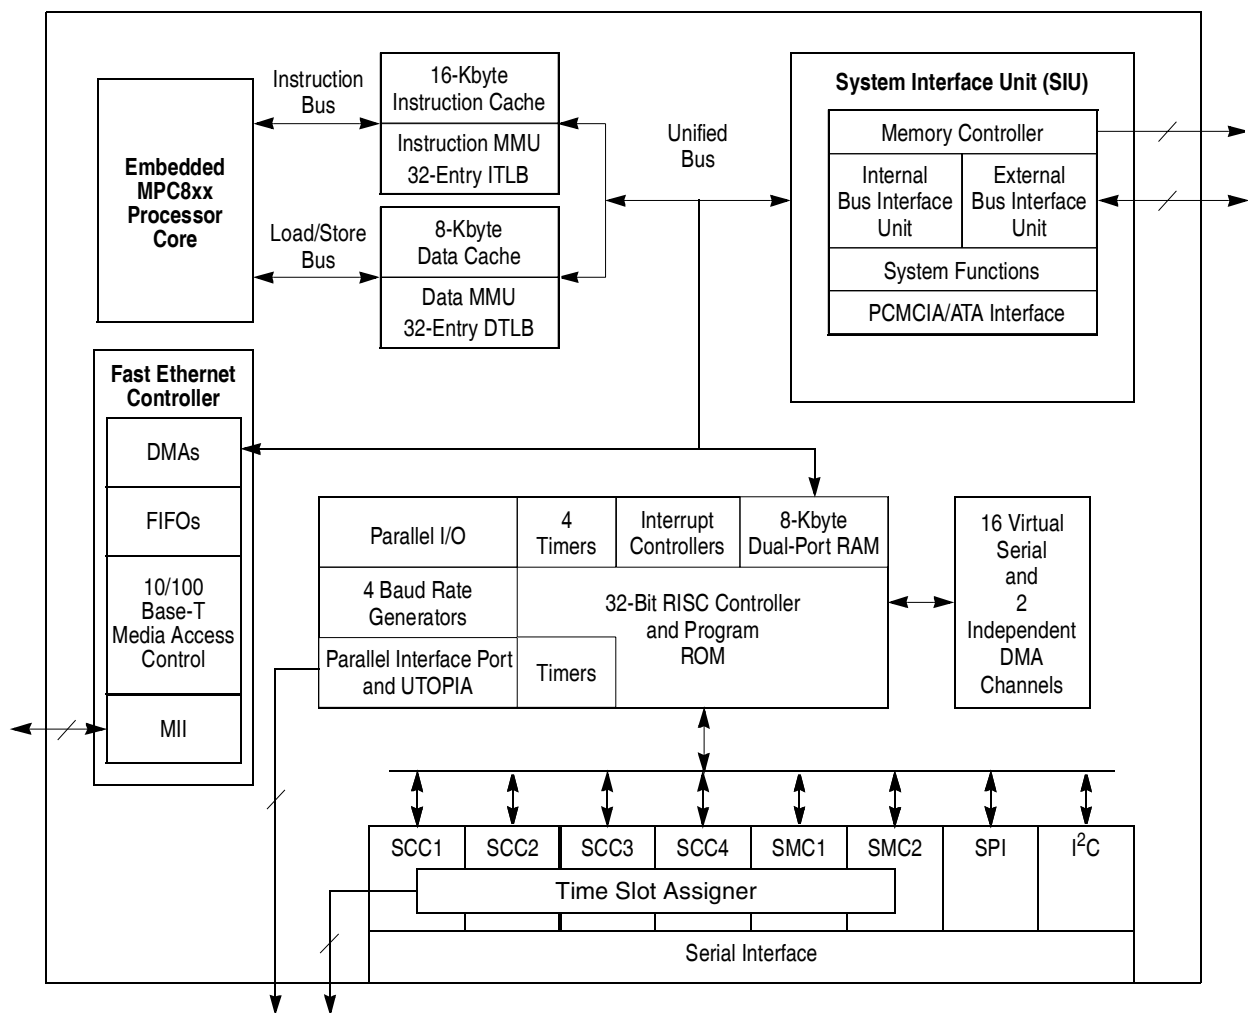

Figure 1. MPC866P Block Diagram

[†] The MPC859P has a 16-Kbyte instruction cache and a 8-Kbyte data cache.

* The MPC859DSL does not contain SMC2 nor the time slot assigner, and provides eight SDMA controllers.

7.5 Experimental Determination

To determine the junction temperature of the device in the application after prototypes are available, the thermal characterization parameter (Ψ_{JT}) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using the following equation:

$$T_J = T_T + (\Psi_{JT} \times P_D)$$

where:

Ψ_{JT} = thermal characterization parameter

T_T = thermocouple temperature on top of package

P_D = power dissipation in package

The thermal characterization parameter is measured per JESD51-2 specification published by JEDEC using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by cooling effects of the thermocouple wire.

¹ For part speeds above 50 MHz, use 9.80 ns for B11a.

² The timing required for \overline{BR} input is relevant when the MPC866/859 is selected to work with the internal bus arbiter. The timing for \overline{BG} input is relevant when the MPC866/859 is selected to work with the external bus arbiter.

³ For part speeds above 50 MHz, use 2 ns for B17.

⁴ The D(0:31) and DP(0:3) input timings B18 and B19 refer to the rising edge of CLKOUT, in which the \overline{TA} input signal is asserted.

⁵ For part speeds above 50 MHz, use 2 ns for B19.

⁶ The D(0:31) and DP(0:3) input timings B20 and B21 refer to the falling edge of CLKOUT. This timing is valid only for read accesses controlled by chip-selects under control of the UPM in the memory controller, for data beats, where DLT3 = 1 in the UPM RAM words. (This is only the case where data is latched on the falling edge of CLKOUT.)

⁷ The timing B30 refers to \overline{CS} when ACS = 00 and to $\overline{WE}(0:3)$ when CSNT = 0.

These synchronous timings define when the $\overline{\text{WAITx}}$ signals are detected in order to freeze (or relieve) the PCMCIA current cycle. The $\overline{\text{WAITx}}$ assertion will be effective only if it is detected 2 cycles before the PSL timer expiration. See PCMCIA Interface in the *MPC866 PowerQUICC User's Manual*.
