Welcome to E-XFL.COM

Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Obsolete
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	-
Number of I/O	57
Number of Gates	3000
Voltage - Supply	3V ~ 3.6V, 4.75V ~ 5.25V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 70°C (TA)
Package / Case	80-TQFP
Supplier Device Package	80-VQFP (14x14)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/a40mx02-1vq80

Silicon Sculptor programs devices independently to achieve the fastest programming times possible. After being programmed, each fuse is verified to insure that it has been programmed correctly. Furthermore, at the end of programming, there are integrity tests that are run to ensure no extra fuses have been programmed. Not only does it test fuses (both programmed and non-programmed), Silicon Sculptor also allows self-test to verify its own hardware extensively.

The procedure for programming an MX device using Silicon Sculptor is as follows:

1. Load the *.AFM file
2. Select the device to be programmed
3. Begin programming

When the design is ready to go to production, Microsemi offers device volume-programming services either through distribution partners or via In-House Programming from the factory.

For more details on programming MX devices, see the *AC225: Programming Antifuse Devices* application note and the *Silicon Sculptor 3 Programmers User Guide*.

3.3.4 Power Supply

MX devices are designed to operate in both 5.0V and 3.3V environments. In particular, 42MX devices can operate in mixed 5.0 V/3.3 V systems. The following table describes the voltage support of MX devices.

Table 6 • **Voltage Support of MX Devices**

Device	VCC	VCCA	VCCI	Maximum Input Tolerance	Nominal Output Voltage
40MX	5.0 V	–	–	5.5 V	5.0 V
	3.3 V	–	–	3.6 V	3.3 V
42MX	–	5.0 V	5.0 V	5.5 V	5.0 V
	–	3.3 V	3.3 V	3.6 V	3.3 V
	–	5.0 V	3.3 V	5.5 V	3.3 V

For A42MX24 and A42MX36 devices the VCCA supply has to be monotonic during power up in order for the POR to issue reset to the JTAG state machine correctly. For more information, see the *AC291: 42MX Family Devices Power-Up Behavior*.

3.3.5 Power-Up/Down in Mixed-Voltage Mode

When powering up 42MX in mixed voltage mode (VCCA = 5.0 V and VCCI = 3.3 V), VCCA must be greater than or equal to VCCI throughout the power-up sequence. If VCCI exceeds VCCA during power-up, one of two things will happen:

- The input protection diode on the I/Os will be forward biased
- The I/Os will be at logical High

In either case, ICC rises to high levels. For power-down, any sequence with VCCA and VCCI can be implemented.

3.3.6 Transient Current

Due to the simultaneous random logic switching activity during power-up, a transient current may appear on the core supply (VCC). Customers must use a regulator for the VCC supply that can source a minimum of 100 mA for transient current during power-up. Failure to provide enough power can prevent the system from powering up properly and result in functional failure. However, there are no reliability concerns, since transient current is distributed across the die instead of confined to a localized spot.

Since the transient current is not due to I/O switching, its value and duration are independent of the VCCI.

3.3.7 Low Power Mode

42MX devices have been designed with a Low Power Mode. This feature, activated with setting the special LP pin to HIGH for a period longer than 800 ns, is particularly useful for battery-operated systems where battery life is a primary concern. In this mode, the core of the device is turned off and the device consumes minimal power with low standby current. In addition, all input buffers are turned off, and all outputs and bidirectional buffers are tristated. Since the core of the device is turned off, the states of the registers are lost. The device must be re-initialized when exiting Low Power Mode. I/Os can be driven during LP mode, and clock pins should be driven HIGH or LOW and should not float to avoid drawing current. To exit LP mode, the LP pin must be pulled LOW for over 200 µs to allow for charge pumps to power up, and device initialization will begin.

3.4 Power Dissipation

The general power consumption of MX devices is made up of static and dynamic power and can be expressed with the following equation.

3.4.1 General Power Equation

$$P = [ICCstandby + ICCactive]*VCCI + IOL*VOL*N + IOH*(VCCI - VOH)*M$$

EQ 1

where:

- ICCstandby is the current flowing when no inputs or outputs are changing.
- ICCactive is the current flowing due to CMOS switching.
- IOL, IOH are TTL sink/source currents.
- VOL, VOH are TTL level output voltages.
- N equals the number of outputs driving TTL loads to VOL.
- M equals the number of outputs driving TTL loads to VOH.

Accurate values for N and M are difficult to determine because they depend on the family type, on design details, and on the system I/O. The power can be divided into two components: static and active.

3.4.2 Static Power Component

The static power due to standby current is typically a small component of the overall power consumption. Standby power is calculated for commercial, worst-case conditions. The static power dissipation by TTL loads depends on the number of outputs driving, and on the DC load current. For instance, a 32-bit bus sinking 4mA at 0.33V will generate 42mW with all outputs driving LOW, and 140mW with all outputs driving HIGH. The actual dissipation will average somewhere in between, as I/Os switch states with time.

3.4.3 Active Power Component

Power dissipation in CMOS devices is usually dominated by the dynamic power dissipation. Dynamic power consumption is frequency-dependent and is a function of the logic and the external I/O. Active power dissipation results from charging internal chip capacitances of the interconnect, unprogrammed antifuses, module inputs, and module outputs, plus external capacitances due to PC board traces and load device inputs. An additional component of the active power dissipation is the totem pole current in the CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent active power dissipation.

The power dissipated by a CMOS circuit can be expressed by the equation:

$$Power(\mu W) = C_{EQ}* \ VCCA2* \ F(1)$$

EQ 2

where:

- C_{EQ} = Equivalent capacitance expressed in picofarads (pF)

f_{q2} = Average second routed array clock rate in MHz)

Table 7 • **Fixed Capacitance Values for MX FPGAs (pF)**

Device Type	r1 routed_Clk1	r2 routed_Clk2
A40MX02	41.4	N/A
A40MX04	68.6	N/A
A42MX09	118	118
A42MX16	165	165
A42MX24	185	185
A42MX36	220	220

3.4.6 Test Circuitry and Silicon Explorer II Probe

MX devices contain probing circuitry that provides built-in access to every node in a design, via the use of Silicon Explorer II. Silicon Explorer II is an integrated hardware and software solution that, in conjunction with the Designer software, allow users to examine any of the internal nets of the device while it is operating in a prototyping or a production system. The user can probe into an MX device without changing the placement and routing of the design and without using any additional resources. Silicon Explorer II's noninvasive method does not alter timing or loading effects, thus shortening the debug cycle and providing a true representation of the device under actual functional situations.

Silicon Explorer II samples data at 100 MHz (asynchronous) or 66 MHz (synchronous). Silicon Explorer II attaches to a PC's standard COM port, turning the PC into a fully functional 18-channel logic analyzer. Silicon Explorer II allows designers to complete the design verification process at their desks and reduces verification time from several hours per cycle to a few seconds.

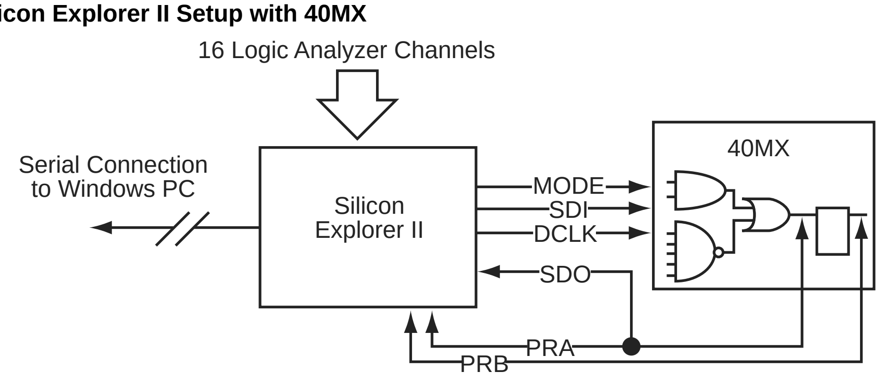
Silicon Explorer II is used to control the MODE, DCLK, SDI and SDO pins in MX devices to select the desired nets for debugging. The user simply assigns the selected internal nets in the Silicon Explorer II software to the PRA/PRB output pins for observation. Probing functionality is activated when the MODE pin is held HIGH.

Figure 12, page 16 illustrates the interconnection between Silicon Explorer II and 40MX devices, while Figure 13, page 17 illustrates the interconnection between Silicon Explorer II and 42MX devices

To allow for probing capabilities, the security fuses must not be programmed. (See User Security, page 12 for the security fuses of 40MX and 42MX devices). Table 8, page 17 summarizes the possible device configurations for probing.

PRA and PRB pins are dual-purpose pins. When the “Reserve Probe Pin” is checked in the Designer software, PRA and PRB pins are reserved as dedicated outputs for probing. If PRA and PRB pins are required as user I/Os to achieve successful layout and “Reserve Probe Pin” is checked, the layout tool will override the option and place user I/Os on PRA and PRB pins.

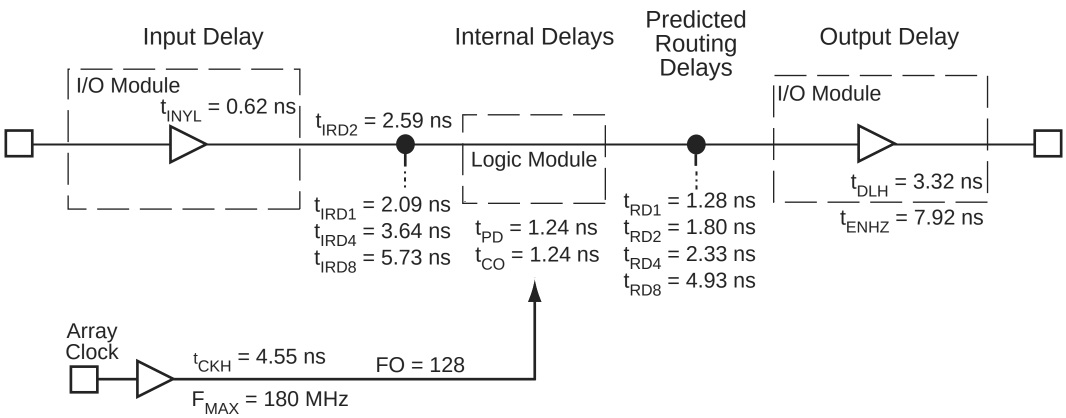
Figure 12 • **Silicon Explorer II Setup with 40MX**



3.10 Timing Models

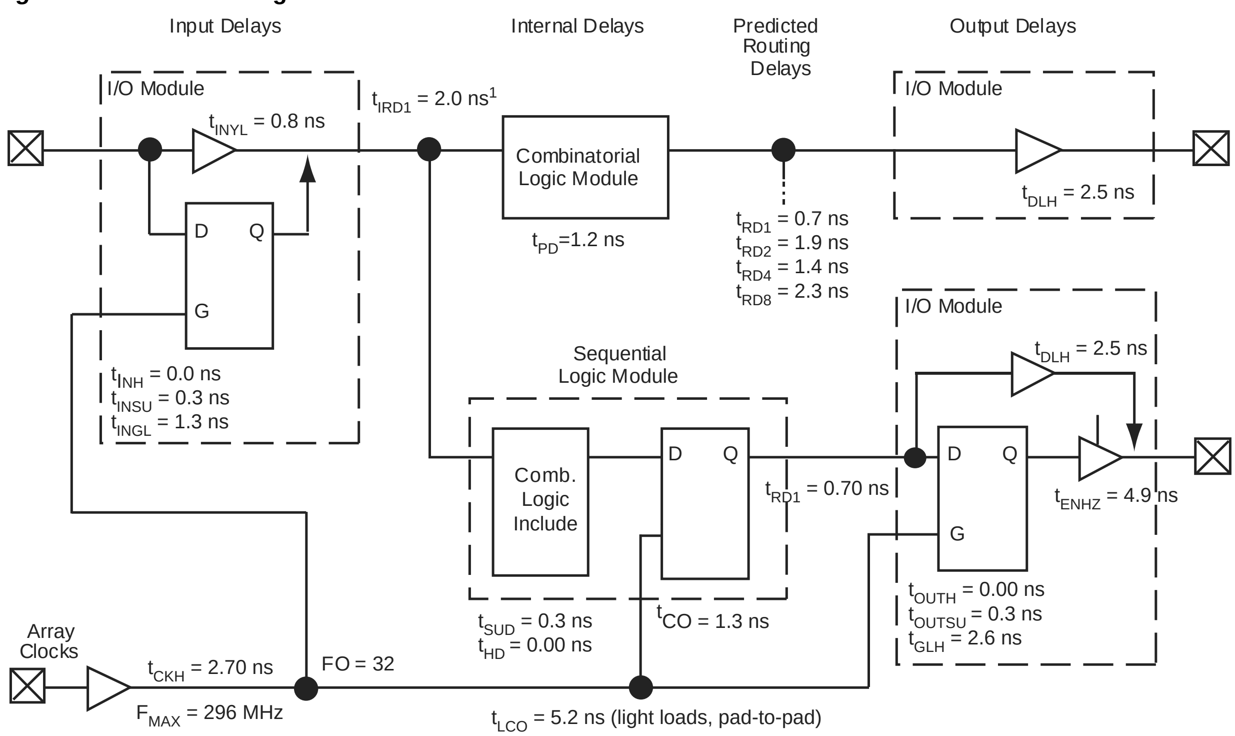
The following figures show various timing models.

Figure 17 • **40MX Timing Model***



Note: Values are shown for 40MX –3 speed devices at 5.0 V worst-case commercial conditions.

Figure 18 • **42MX Timing Model**



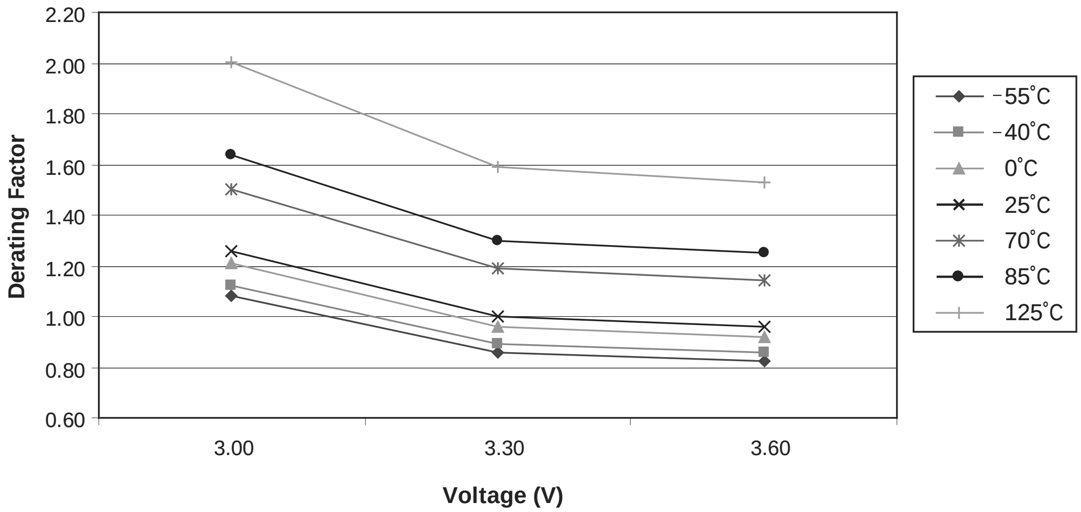
Note: 1. Input module predicted routing delay

Note: 2. Values are shown for A42MX09 –3 at 5.0 V worst-case commercial conditions.

Table 31 • **40MX Temperature and Voltage Derating Factors (Normalized to TJ = 25°C, VCC = 3.3 V)**

	Temperature						
40MX Voltage	**–55°C**	**–40°C**	**0°C**	**25°C**	**70°C**	**85°C**	**125°C**
3.60	0.83	0.85	0.92	0.96	1.14	1.25	1.53

Figure 37 • **40MX Junction Temperature and Voltage Derating Curves (Normalized to T_J = 25°C, VCC = 3.3 V)**



Note: This derating factor applies to all routing and propagation delays

3.11.5 PCI System Timing Specification

The following tables list the critical PCI timing parameters and the corresponding timing parameters for the MX PCI-compliant devices.

3.11.6 PCI Models

Microsemi provides synthesizable VHDL and Verilog-HDL models for a PCI Target interface, a PCI Target and Target+DMA Master interface. Contact the Microsemi sales representative for more details.

Table 32 • **Clock Specification for 33 MHz PCI**

		PCI		A42MX24		A42MX36		
Symbol	**Parameter**	**Min.**	**Max.**	**Min.**	**Max.**	**Min.**	**Max.**	**Units**

d_{THL}	Delta HIGH to LOW		0.03		0.03		0.04		0.04		0.06	ns/pF

1. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual performance.
2. Set-up times assume fanout of 3. Further testing information can be obtained from the Timer utility.
3. The hold time for the DFME1A macro may be greater than 0 ns. Use the Timer tool from the Designer software to check the hold time for this macro.
4. Delays based on 35 pF loading.

Table 38 • A42MX09 Timing Characteristics (Nominal 5.0 V Operation) (Worst-Case Commercial Conditions, VCCA = 4.75 V, T_J = 70°C)

t_{ILA}	Latch Active Pulse Width	6.5		7.3		8.2		9.7		13.5		ns

Clock signal to shift the Boundary Scan Test (BST) data into the device. This pin functions as an I/O when "Reserve JTAG" is not checked in the Designer Software. BST pins are only available in A42MX24 and A42MX36 devices.

TDI, I/OTest Data In

Serial data input for BST instructions and data. Data is shifted in on the rising edge of TCK. This pin functions as an I/O when "Reserve JTAG" is not checked in the Designer Software. BST pins are only available in A42MX24 and A42MX36 devices.

TDO, I/OTest Data Out

Serial data output for BST instructions and test data. This pin functions as an I/O when "Reserve JTAG" is not checked in the Designer Software. BST pins are only available in A42MX24 and A42MX36 devices.

TMS, I/OTest Mode Select

The TMS pin controls the use of the IEEE 1149.1 Boundary Scan pins (TCK, TDI, TDO). In flexible mode when the TMS pin is set LOW, the TCK, TDI and TDO pins are boundary scan pins. Once the boundary scan pins are in test mode, they will remain in that mode until the internal boundary scan state machine reaches the "logic reset" state. At this point, the boundary scan pins will be released and will function as regular I/O pins. The "logic reset" state is reached 5 TCK cycles after the TMS pin is set HIGH. In dedicated test mode, TMS functions as specified in the IEEE 1149.1 specifications. IEEE JTAG specification recommends a 10kΩ pull-up resistor on the pin. BST pins are only available in A42MX24 and A42MX36 devices.

VCC, Supply Voltage

Input supply voltage for 40MX devices

VCCA, Supply Voltage

Supply voltage for array in 42MX devices

VCCI, Supply Voltage

Supply voltage for I/Os in 42MX devices

WD, I/OWide Decode Output

When a wide decode module is used in a 42MX device this pin can be used as a dedicated output from the wide decode module. This direct connection eliminates additional interconnect delays associated with regular logic modules. To implement the direct I/O connection, connect an output buffer of any type to the output of the wide decode macro and place this output on one of the reserved WD pins.
