Welcome to E-XFL.COM

Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Active
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	-
Number of I/O	57
Number of Gates	3000
Voltage - Supply	3V ~ 3.6V, 4.5V ~ 5.5V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 85°C (TA)
Package / Case	80-TQFP
Supplier Device Package	80-VQFP (14x14)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/a40mx02-1vqg80i

About Microsemi

Microsemi Corporation (Nasdaq: MSCC) offers a comprehensive portfolio of semiconductor and system solutions for aerospace & defense, communications, data center and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world's standard for time; voice processing devices; RF solutions; discrete components; enterprise storage and communication solutions, security technologies and scalable anti-tamper products; Ethernet solutions; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. Microsemi is headquartered in Aliso Viejo, California, and has approximately 4,800 employees globally. Learn more at www.microsemi.com.

3.3.7 Low Power Mode

42MX devices have been designed with a Low Power Mode. This feature, activated with setting the special LP pin to HIGH for a period longer than 800 ns, is particularly useful for battery-operated systems where battery life is a primary concern. In this mode, the core of the device is turned off and the device consumes minimal power with low standby current. In addition, all input buffers are turned off, and all outputs and bidirectional buffers are tristated. Since the core of the device is turned off, the states of the registers are lost. The device must be re-initialized when exiting Low Power Mode. I/Os can be driven during LP mode, and clock pins should be driven HIGH or LOW and should not float to avoid drawing current. To exit LP mode, the LP pin must be pulled LOW for over 200 µs to allow for charge pumps to power up, and device initialization will begin.

3.4 Power Dissipation

The general power consumption of MX devices is made up of static and dynamic power and can be expressed with the following equation.

3.4.1 General Power Equation

$$P = [ICCstandby + ICCactive]*VCCI + IOL*VOL*N + IOH*(VCCI - VOH)*M$$

EQ 1

where:

- ICCstandby is the current flowing when no inputs or outputs are changing.
- ICCactive is the current flowing due to CMOS switching.
- IOL, IOH are TTL sink/source currents.
- VOL, VOH are TTL level output voltages.
- N equals the number of outputs driving TTL loads to VOL.
- M equals the number of outputs driving TTL loads to VOH.

Accurate values for N and M are difficult to determine because they depend on the family type, on design details, and on the system I/O. The power can be divided into two components: static and active.

3.4.2 Static Power Component

The static power due to standby current is typically a small component of the overall power consumption. Standby power is calculated for commercial, worst-case conditions. The static power dissipation by TTL loads depends on the number of outputs driving, and on the DC load current. For instance, a 32-bit bus sinking 4mA at 0.33V will generate 42mW with all outputs driving LOW, and 140mW with all outputs driving HIGH. The actual dissipation will average somewhere in between, as I/Os switch states with time.

3.4.3 Active Power Component

Power dissipation in CMOS devices is usually dominated by the dynamic power dissipation. Dynamic power consumption is frequency-dependent and is a function of the logic and the external I/O. Active power dissipation results from charging internal chip capacitances of the interconnect, unprogrammed antifuses, module inputs, and module outputs, plus external capacitances due to PC board traces and load device inputs. An additional component of the active power dissipation is the totem pole current in the CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent active power dissipation.

The power dissipated by a CMOS circuit can be expressed by the equation:

$$Power(\mu W) = C_{EQ} * VCCA2 * F(1)$$

EQ 2

where:

- C_{EQ} = Equivalent capacitance expressed in picofarads (pF)

Figure 13 • **Silicon Explorer II Setup with 42MX**

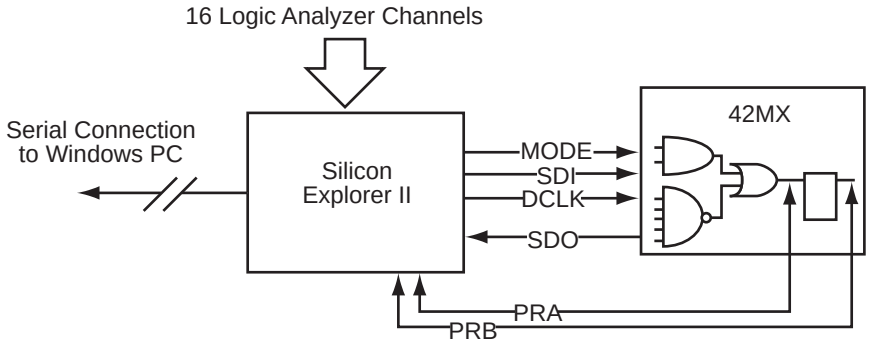

Table 8 • **Device Configuration Options for Probe Capability**

Security Fuse(s) Programmed	Mode	PRA, PRB[1]	SDI, SDO, DCLK[1]
No	LOW	User I/Os[2]	User I/Os[2]
No	HIGH	Probe Circuit Outputs	Probe Circuit Inputs
Yes	–	Probe Circuit Secured	Probe Circuit Secured

1. *Avoid using SDI, SDO, DCLK, PRA and PRB pins as input or bidirectional ports. Since these pins are active during probing, input signals will not pass through these pins and may cause contention.*
2. *If no user signal is assigned to these pins, they will behave as unused I/Os in this mode. See the Pin Descriptions,* page 83 *for information on unused I/O pins*

3.4.7 Design Consideration

It is recommended to use a series 70Ω termination resistor on every probe connector (SDI, SDO, MODE, DCLK, PRA and PRB). The 70 Ω series termination is used to prevent data transmission corruption during probing and reading back the checksum.

3.4.8 IEEE Standard 1149.1 Boundary Scan Test (BST) Circuitry

42MX24 and 42MX36 devices are compatible with IEEE Standard 1149.1 (informally known as Joint Testing Action Group Standard or JTAG), which defines a set of hardware architecture and mechanisms for cost-effective board-level testing. The basic MX boundary-scan logic circuit is composed of the TAP (test access port), TAP controller, test data registers and instruction register (Figure 14, page 18). This circuit supports all mandatory IEEE 1149.1 instructions (EXTEST, SAMPLE/PRELOAD and BYPASS) and some optional instructions. Table 9, page 18 describes the ports that control JTAG testing, while Table 10, page 18 describes the test instructions supported by these MX devices.

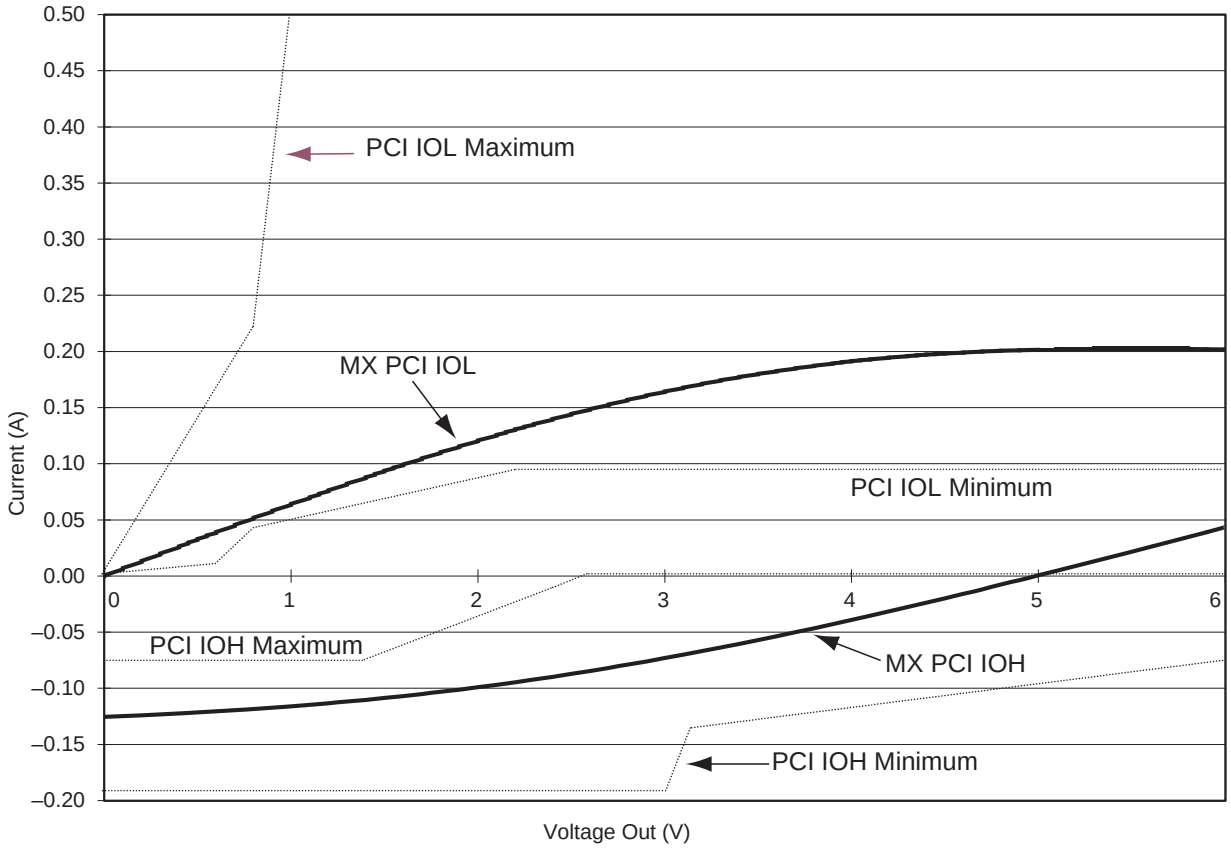
Each test section is accessed through the TAP, which has four associated pins: TCK (test clock input), TDI and TDO (test data input and output), and TMS (test mode selector).

The TAP controller is a four-bit state machine. The '1's and '0's represent the values that must be present at TMS at a rising edge of TCK for the given state transition to occur. IR and DR indicate that the instruction register or the data register is operating in that state.

The TAP controller receives two control inputs (TMS and TCK) and generates control and clock signals for the rest of the test logic architecture. On power-up, the TAP controller enters the Test-Logic-Reset state. To guarantee a reset of the controller from any of the possible states, TMS must remain high for five TCK cycles.

42MX24 and 42MX36 devices support three types of test data registers: bypass, device identification, and boundary scan. The bypass register is selected when no other register needs to be accessed in a device. This speeds up test data transfer to other devices in a test data path. The 32-bit device identification register is a shift register with four fields (lowest significant byte (LSB), ID number, part number and version). The boundary-scan register observes and controls the state of each I/O pin.

Figure 16 • **Typical Output Drive Characteristics (Based Upon Measured Data)**



3.9.4 Junction Temperature (T_J)

The temperature variable in the Designer software refers to the junction temperature, not the ambient temperature. This is an important distinction because the heat generated from dynamic power consumption is usually hotter than the ambient temperature. The following equation can be used to calculate junction temperature.

$$\text{Junction Temperature} = \Delta T + T_a \quad (1)$$

EQ 4

where:

- T_a = Ambient Temperature
- ΔT = Temperature gradient between junction (silicon) and ambient
- $\Delta T = \theta_{ja} * P$ (2)
- P = Power
- θ_{ja} = Junction to ambient of package. θ_{ja} numbers are located in Table 27, page 29.

3.9.5 Package Thermal Characteristics

The device junction-to-case thermal characteristic is θ_{jc}, and the junction-to-ambient air characteristic is θ_{ja}. The thermal characteristics for θ_{ja} are shown with two different air flow rates.

The maximum junction temperature is 150°C.

Maximum power dissipation for commercial- and industrial-grade devices is a function of θ_{ja}.

approximately a 3 ns to a 6 ns delay, which is represented statistically in higher fanout (FO=8) routing delays in the data sheet specifications section, shown in Table 34, page 41.

3.11.3 Timing Derating

MX devices are manufactured with a CMOS process. Therefore, device performance varies according to temperature, voltage, and process changes. Minimum timing parameters reflect maximum operating voltage, minimum operating temperature and best-case processing. Maximum timing parameters reflect minimum operating voltage, maximum operating temperature and worst-case processing.

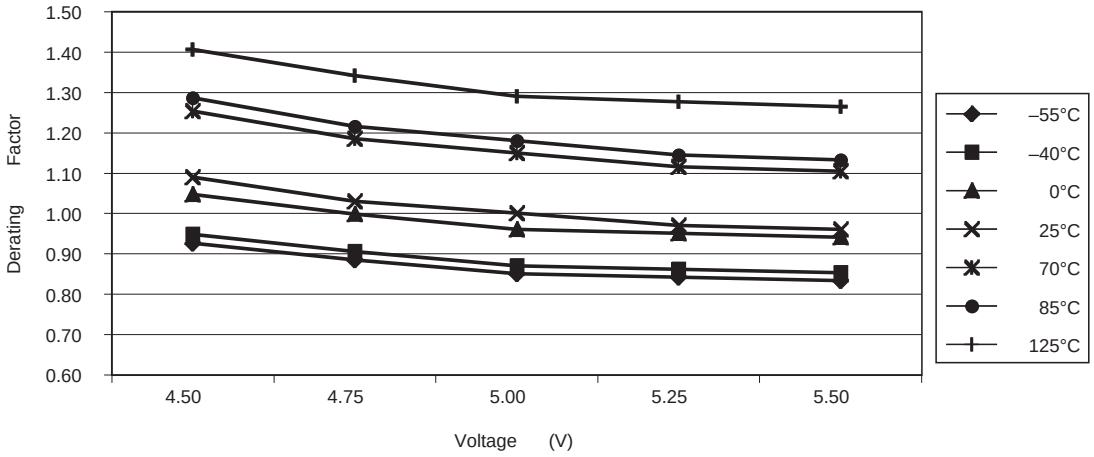
3.11.4 Temperature and Voltage Derating Factors

The following tables and figures show temperature and voltage derating factors for 40MX and 42MX FPGAs.

Table 28 • **42MX Temperature and Voltage Derating Factors (Normalized to T_J = 25°C, VCCA = 5.0 V)**

	Temperature						
42MX Voltage	**–55°C**	**–40°C**	**0°C**	**25°C**	**70°C**	**85°C**	**125°C**
4.50	0.93	0.95	1.05	1.09	1.25	1.29	1.41
4.75	0.88	0.90	1.00	1.03	1.18	1.22	1.34
5.00	0.85	0.87	0.96	1.00	1.15	1.18	1.29
5.25	0.84	0.86	0.95	0.97	1.12	1.14	1.28
5.50	0.83	0.85	0.94	0.96	1.10	1.13	1.26

Figure 34 • **42MX Junction Temperature and Voltage Derating Curves (Normalized to TJ = 25°C, VCCA = 5.0 V)**



Note: This derating factor applies to all routing and propagation delays

Table 29 • **40MX Temperature and Voltage Derating Factors(Normalized to TJ = 25°C, VCC = 5.0 V)**

	Temperature						
40MX Voltage	**–55°C**	**–40°C**	**0°C**	**25°C**	**70°C**	**85°C**	**125°C**

1. *For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDn}$, $t_{CO} + t_{RD1} + t_{PDn}$, or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.*
2. *Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual performance.*
3. *Data applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the Timer utility.*
4. *Set-up and hold timing parameters for the input buffer latch are defined with respect to the PAD and the D input. External setup/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal setup (hold) time.*
5. *Delays based on 35 pF loading.*

t_{GHL}	G-to-Pad LOW		4.9		5.4		6.2		7.2		10.1	ns
t_{LSU}	I/O Latch Set-Up	0.5		0.5		0.6		0.7		1.0		ns
t_{LH}	I/O Latch Hold	0.0		0.0		0.0		0.0		0.0		ns
t_{LCO}	I/O Latch Clock-to-Out (Pad-to-Pad) 32 I/O		5.5		6.1		6.9		8.1		11.3	ns
t_{ACO}	Array Latch Clock-to-Out (Pad-to-Pad) 32 I/O		10.6		11.8		13.4		15.7		22.0	ns
d_{TLH}	Capacitive Loading, LOW to HIGH		0.04		0.04		0.04		0.05		0.07	ns/pF
d_{THL}	Capacitive Loading, HIGH to LOW		0.03		0.03		0.03		0.04		0.06	ns/pF

1. For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDn}$, $t_{CO} + t_{RD1} + t_{PDn}$, or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.
2. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual performance.
3. D*ata applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the Timer utility.*
4. Set-up and hold timing parameters for the Input Buffer Latch are defined with respect to the PAD and the D input. External setup/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal setup (hold) time.
5. Delays based on 35 pF loading

Table 43 • **A42MX24 Timing Characteristics (Nominal 3.3 V Operation) (Worst-Case Commercial Conditions, VCCA = 3.0 V, T_J = 70°C)**

Parameter / Description		–3 Speed		–2 Speed		–1 Speed		Std Speed		–F Speed		Units
		Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.	
Logic Module Combinatorial Functions[1]												
t_{PD}	Internal Array Module Delay		2.0		1.8		2.1		2.5		3.4	ns
t_{PDD}	Internal Decode Module Delay		1.1		2.2		2.5		3.0		4.2	ns
Logic Module Predicted Routing Delays[2]												
t_{RD1}	FO = 1 Routing Delay		1.7		1.3		1.4		1.7		2.3	ns
t_{RD2}	FO = 2 Routing Delay		2.0		1.6		1.8		2.1		3.0	ns
t_{RD3}	FO = 3 Routing Delay		1.1		2.0		2.2		2.6		3.7	ns
t_{RD4}	FO = 4 Routing Delay		1.5		2.3		2.6		3.1		4.3	ns
t_{RD5}	FO = 8 Routing Delay		1.8		3.7		4.2		5.0		7.0	ns
