Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Figure 2 • 42MX C-Module Implementation

The 42MX devices contain three types of logic modules: combinatorial (C-modules), sequential (S-modules) and decode (D-modules). The following figure illustrates the combinatorial logic module. The S-module, shown in Figure 4, page 8, implements the same combinatorial logic function as the C-module while adding a sequential element. The sequential element can be configured as either a D-flip-flop or a transparent latch. The S-module register can be bypassed so that it implements purely combinatorial logic.

- F = Switching frequency in megahertz (MHz)

3.4.4 Equivalent Capacitance

Equivalent capacitance is calculated by measuring ICCactive at a specified frequency and voltage for each circuit component of interest. Measurements have been made over a range of frequencies at a fixed value of VCC. Equivalent capacitance is frequency-independent, so the results can be used over a wide range of operating conditions. Equivalent capacitance values are shown below.

3.4.5 C_{EQ} Values for Microsemi MX FPGAs

Modules (C_{EQM})3.5

Input Buffers (C_{EQI})6.9

Output Buffers (C_{EQO})18.2

Routed Array Clock Buffer Loads (C_{EQCR})1.4

To calculate the active power dissipated from the complete design, the switching frequency of each part of the logic must be known. The equation below shows a piece-wise linear summation over all components.

$$\text{Power} = \text{VCCA}^2 * [(m * C_{EQM} * f_m)_{\text{modules}} + (n * C_{EQI} * f_n)_{\text{inputs}} + (p * (C_{EQO} + C_L) * f_p)_{\text{outputs}} + \\ 0.5 * (q_1 * C_{EQCR} * f_{q1})_{\text{routed_Clk1}} + (r_1 * f_{q1})_{\text{routed_Clk1}} + \\ 0.5 * (q_2 * C_{EQCR} * f_{q2})_{\text{routed_Clk2}} + (r_2 * f_{q2})_{\text{routed_Clk2}}(2)]$$

EQ 3

where:

m = Number of logic modules switching at frequency f_m

n = Number of input buffers switching at frequency f_n

p = Number of output buffers switching at frequency f_p

q₁ = Number of clock loads on the first routed array clock

q₂ = Number of clock loads on the second routed array clock

r₁ = Fixed capacitance due to first routed array clock

r₂ = Fixed capacitance due to second routed array clock

C_{EQM} = Equivalent capacitance of logic modules in pF

reliability. Devices should not be operated outside the recommended operating conditions.

- For dual-module macros, use $t_{PD1} + t_{RD1} + t_{PDn}$, $t_{CO} + t_{RD1} + t_{PDn}$, or $t_{PD1} + t_{RD1} + t_{SUD}$, whichever is appropriate.
- Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual performance.
- Data applies to macros based on the S-module. Timing parameters for sequential macros constructed from C-modules can be obtained from the Timer utility.
- Set-up and hold timing parameters for the input buffer latch are defined with respect to the PAD and the D input. External setup/hold timing parameters must account for delay from an external PAD signal to the G inputs. Delay from an external PAD signal to the G input subtracts (adds) to the internal setup (hold) time.
- Delays based on 35 pF loading.
