

Welcome to [E-XFL.COM](#)

[Understanding Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Obsolete
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	-
Number of I/O	34
Number of Gates	3000
Voltage - Supply	3V ~ 3.6V, 4.75V ~ 5.25V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 70°C (TA)
Package / Case	44-LCC (J-Lead)
Supplier Device Package	44-PLCC (16.59x16.59)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/a40mx02-pl44

3.2.3.3 Antifuse Structures

An antifuse is a “normally open” structure. The use of antifuses to implement a programmable logic device results in highly testable structures as well as efficient programming algorithms. There are no pre-existing connections; temporary connections can be made using pass transistors. These temporary connections can isolate individual antifuses to be programmed and individual circuit structures to be tested, which can be done before and after programming. For instance, all metal tracks can be tested for continuity and shorts between adjacent tracks, and the functionality of all logic modules can be verified.

Figure 7 • MX Routing Structure

3.2.4 Clock Networks

The 40MX devices have one global clock distribution network (CLK). A signal can be put on the CLK network by being routed through the CLKBUF buffer.

In 42MX devices, there are two low-skew, high-fanout clock distribution networks, referred to as CLKA and CLKB. Each network has a clock module (CLKMOD) that can select the source of the clock signal from any of the following (Figure 8, page 11):

- Externally from the CLKA pad, using CLKBUF buffer
- Externally from the CLKB pad, using CLKBUF buffer
- Internally from the CLKINTA input, using CLKINT buffer
- Internally from the CLKINTB input, using CLKINT buffer

The clock modules are located in the top row of I/O modules. Clock drivers and a dedicated horizontal clock track are located in each horizontal routing channel.

Clock input pads in both 40MX and 42MX devices can also be used as normal I/Os, bypassing the clock networks.

The A42MX36 device has four additional register control resources, called quadrant clock networks (Figure 9, page 11). Each quadrant clock provides a local, high-fanout resource to the contiguous logic modules within its quadrant of the device. Quadrant clock signals can originate from specific I/O pins or from the internal array and can be used as a secondary register clock, register clear, or output enable.

3.4.9 JTAG Mode Activation

The JTAG test logic circuit is activated in the Designer software by selecting **Tools > Device Selection**. This brings up the Device Selection dialog box as shown in the following figure. The JTAG test logic circuit can be enabled by clicking the “Reserve JTAG Pins” check box. The following table explains the pins’ behavior in either mode.

Figure 15 • Device Selection Wizard

Table 11 • Boundary Scan Pin Configuration and Functionality

Reserve JTAG	Checked	Unchecked
TCK	BST input; must be terminated to logical HIGH or LOW to avoid floating	User I/O
TDI, TMS	BST input; may float or be tied to HIGH	User I/O
TDO	BST output; may float or be connected to TDI of another device	User I/O

3.4.10 TRST Pin and TAP Controller Reset

An active reset (TRST) pin is not supported; however, MX devices contain power-on circuitry that resets the boundary scan circuitry upon power-up. Also, the TMS pin is equipped with an internal pull-up resistor. This allows the TAP controller to remain in or return to the Test-Logic-Reset state when there is no input or when a logical 1 is on the TMS pin. To reset the controller, TMS must be HIGH for at least five TCK cycles.

3.4.11 Boundary Scan Description Language (BSDL) File

Conforming to the IEEE Standard 1149.1 requires that the operation of the various JTAG components be documented. The BSDL file provides the standard format to describe the JTAG components that can be used by automatic test equipment software. The file includes the instructions that are supported, instruction bit pattern, and the boundary-scan chain order. For an in-depth discussion on BSDL files, see the *BSDL Files Format Description* application note.

BSDL files are grouped into two categories - generic and device-specific. The generic files assign all user I/Os as inouts. Device-specific files assign user I/Os as inputs, outputs or inouts.

Generic files for MX devices are available on the Microsemi SoC Product Group's website:

<http://www.microsemi.com/soc/techdocs/models/bsdl.html>.

3.5 Development Tool Support

The MX family of FPGAs is fully supported by Libero® Integrated Design Environment (IDE). Libero IDE is a design management environment, seamlessly integrating design tools while guiding the user through the design flow, managing all design and log files, and passing necessary design data among tools. Libero IDE allows users to integrate both schematic and HDL synthesis into a single flow and verify the entire design in a single environment. Libero IDE includes SynplifyPro from Synopsys, ModelSim® HDL Simulator from Mentor Graphics® and Viewdraw.

Libero IDE includes place-and-route and provides a comprehensive suite of backend support tools for FPGA development, including timing-driven place-and-route, and a world-class integrated static timing analyzer and constraints editor.

Figure 33 • 42MX SRAM Asynchronous Read Operation—Type 2 (Write Address Controlled)

3.10.7 Predictable Performance: Tight Delay Distributions

Propagation delay between logic modules depends on the resistive and capacitive loading of the routing tracks, the interconnect elements, and the module inputs being driven. Propagation delay increases as the length of routing tracks, the number of interconnect elements, or the number of inputs increases.

From a design perspective, the propagation delay can be statistically correlated or modeled by the fanout (number of loads) driven by a module. Higher fanout usually requires some paths to have longer routing tracks.

The MX FPGAs deliver a tight fanout delay distribution, which is achieved in two ways: by decreasing the delay of the interconnect elements and by decreasing the number of interconnect elements per path.

Microsemi's patented antifuse offers a very low resistive/capacitive interconnect. The antifuses, fabricated in 0.45 µm lithography, offer nominal levels of 100 Ω resistance and 7.0 fF capacitance per antifuse.

MX fanout distribution is also tight due to the low number of antifuses required for each interconnect path. The proprietary architecture limits the number of antifuses per path to a maximum of four, with 90 percent of interconnects using only two antifuses.

3.11 Timing Characteristics

Device timing characteristics fall into three categories: family-dependent, device-dependent, and design-dependent. The input and output buffer characteristics are common to all MX devices. Internal routing delays are device-dependent; actual delays are not determined until after place-and-route of the user's design is complete. Delay values may then be determined by using the Designer software utility or by performing simulation with post-layout delays.

3.11.1 Critical Nets and Typical Nets

Propagation delays are expressed only for typical nets, which are used for initial design performance evaluation. Critical net delays can then be applied to the most timing critical paths. Critical nets are determined by net property assignment in Microsemi's Designer software prior to placement and routing. Up to 6% of the nets in a design may be designated as critical.

3.11.2 Long Tracks

Some nets in the design use long tracks, which are special routing resources that span multiple rows, columns, or modules. Long tracks employ three and sometimes four antifuse connections, which increase capacitance and resistance, resulting in longer net delays for macros connected to long tracks. Typically, up to 6 percent of nets in a fully utilized device require long tracks. Long tracks add
