Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

3 40MX and 42MX FPGAs

3.1 General Description

Microsemi's 40MX and 42MX families offer a cost-effective design solution at 5V. The MX devices are single-chip solutions and provide high performance while shortening the system design and development cycle. MX devices can integrate and consolidate logic implemented in multiple PALs, CPLDs, and FPGAs. Example applications include high-speed controllers and address decoding, peripheral bus interfaces, DSP, and co-processor functions.

The MX device architecture is based on Microsemi's patented antifuse technology implemented in a 0.45µm triple-metal CMOS process. With capacities ranging from 3,000 to 54,000 system gates, the MX devices provide performance up to 250 MHz, are live on power-up and have one-fifth the standby power consumption of comparable FPGAs. MX FPGAs provide up to 202 user I/Os and are available in a wide variety of packages and speed grades.

A42MX24 and A42MX36 devices also feature multiPlex I/Os, which support mixed-voltage systems, enable programmable PCI, deliver high-performance operation at both 5.0V and 3.3V, and provide a low-power mode. The devices are fully compliant with the PCI local bus specification (version 2.1). They deliver 200 MHz on-chip operation and 6.1 ns clock-to-output performance.

The 42MX24 and 42MX36 devices include system-level features such as IEEE Standard 1149.1 (JTAG) Boundary Scan Testing and fast wide-decode modules. In addition, the A42MX36 device offers dual-port SRAM for implementing fast FIFOs, LIFOs, and temporary data storage. The storage elements can efficiently address applications requiring wide data path manipulation and can perform transformation functions such as those required for telecommunications, networking, and DSP.

All MX devices are fully tested over automotive and military temperature ranges. In addition, the largest member of the family, the A42MX36, is available in both CQ208 and CQ256 ceramic packages screened to MIL-STD-883 levels. For easy prototyping and conversion from plastic to ceramic, the CQ208 and PQ208 devices are pin-compatible.

3.2 MX Architectural Overview

The MX devices are composed of fine-grained building blocks that enable fast, efficient logic designs. All devices within these families are composed of logic modules, I/O modules, routing resources and clock networks, which are the building blocks for fast logic designs. In addition, the A42MX36 device contains embedded dual-port SRAM modules, which are optimized for high-speed data path functions such as FIFOs, LIFOs and scratch pad memory. A42MX24 and A42MX36 also contain wide-decode modules.

3.2.1 Logic Modules

The 40MX logic module is an eight-input, one-output logic circuit designed to implement a wide range of logic functions with efficient use of interconnect routing resources.(see the following figure).

The logic module can implement the four basic logic functions (NAND, AND, OR and NOR) in gates of two, three, or four inputs. The logic module can also implement a variety of D-latches, exclusivity functions, AND-ORs and OR-ANDs. No dedicated hard-wired latches or flip-flops are required in the array; latches and flip-flops can be constructed from logic modules whenever required in the application.

Silicon Sculptor programs devices independently to achieve the fastest programming times possible. After being programmed, each fuse is verified to insure that it has been programmed correctly. Furthermore, at the end of programming, there are integrity tests that are run to ensure no extra fuses have been programmed. Not only does it test fuses (both programmed and non-programmed), Silicon Sculptor also allows self-test to verify its own hardware extensively.

The procedure for programming an MX device using Silicon Sculptor is as follows:

1. Load the *.AFM file
2. Select the device to be programmed
3. Begin programming

When the design is ready to go to production, Microsemi offers device volume-programming services either through distribution partners or via In-House Programming from the factory.

For more details on programming MX devices, see the *AC225: Programming Antifuse Devices* application note and the *Silicon Sculptor 3 Programmers User Guide*.

3.3.4 Power Supply

MX devices are designed to operate in both 5.0V and 3.3V environments. In particular, 42MX devices can operate in mixed 5.0 V/3.3 V systems. The following table describes the voltage support of MX devices.

Table 6 • Voltage Support of MX Devices

Device	VCC	VCCA	VCCI	Maximum Input Tolerance	Nominal Output Voltage
40MX	5.0 V	–	–	5.5 V	5.0 V
	3.3 V	–	–	3.6 V	3.3 V
42MX	–	5.0 V	5.0 V	5.5 V	5.0 V
	–	3.3 V	3.3 V	3.6 V	3.3 V
	–	5.0 V	3.3 V	5.5 V	3.3 V

For A42MX24 and A42MX36 devices the VCCA supply has to be monotonic during power up in order for the POR to issue reset to the JTAG state machine correctly. For more information, see the *AC291: 42MX Family Devices Power-Up Behavior*.

3.3.5 Power-Up/Down in Mixed-Voltage Mode

When powering up 42MX in mixed voltage mode (VCCA = 5.0 V and VCCI = 3.3 V), VCCA must be greater than or equal to VCCI throughout the power-up sequence. If VCCI exceeds VCCA during power-up, one of two things will happen:

- The input protection diode on the I/Os will be forward biased
- The I/Os will be at logical High

In either case, ICC rises to high levels. For power-down, any sequence with VCCA and VCCI can be implemented.

3.3.6 Transient Current

Due to the simultaneous random logic switching activity during power-up, a transient current may appear on the core supply (VCC). Customers must use a regulator for the VCC supply that can source a minimum of 100 mA for transient current during power-up. Failure to provide enough power can prevent the system from powering up properly and result in functional failure. However, there are no reliability concerns, since transient current is distributed across the die instead of confined to a localized spot.

Since the transient current is not due to I/O switching, its value and duration are independent of the VCCI.
