### Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

### Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

#### Details

|                                |                                                                                                                                                                 |

### 3.3.7 Low Power Mode

42MX devices have been designed with a Low Power Mode. This feature, activated with setting the special LP pin to HIGH for a period longer than 800 ns, is particularly useful for battery-operated systems where battery life is a primary concern. In this mode, the core of the device is turned off and the device consumes minimal power with low standby current. In addition, all input buffers are turned off, and all outputs and bidirectional buffers are tristated. Since the core of the device is turned off, the states of the registers are lost. The device must be re-initialized when exiting Low Power Mode. I/Os can be driven during LP mode, and clock pins should be driven HIGH or LOW and should not float to avoid drawing current. To exit LP mode, the LP pin must be pulled LOW for over 200  $\mu$ s to allow for charge pumps to power up, and device initialization will begin.

## 3.4 Power Dissipation

The general power consumption of MX devices is made up of static and dynamic power and can be expressed with the following equation.

### 3.4.1 General Power Equation

$$P = [ICC_{standby} + ICC_{active}] * V_{CCI} + IOL * VOL * N + IOH * (V_{CCI} - VOH) * M$$

EQ 1

where:

- $ICC_{standby}$  is the current flowing when no inputs or outputs are changing.
- $ICC_{active}$  is the current flowing due to CMOS switching.
- $IOL$ ,  $IOH$  are TTL sink/source currents.
- $VOL$ ,  $VOH$  are TTL level output voltages.
- $N$  equals the number of outputs driving TTL loads to  $VOL$ .
- $M$  equals the number of outputs driving TTL loads to  $VOH$ .

Accurate values for  $N$  and  $M$  are difficult to determine because they depend on the family type, on design details, and on the system I/O. The power can be divided into two components: static and active.

### 3.4.2 Static Power Component

The static power due to standby current is typically a small component of the overall power consumption. Standby power is calculated for commercial, worst-case conditions. The static power dissipation by TTL loads depends on the number of outputs driving, and on the DC load current. For instance, a 32-bit bus sinking 4mA at 0.33V will generate 42mW with all outputs driving LOW, and 140mW with all outputs driving HIGH. The actual dissipation will average somewhere in between, as I/Os switch states with time.

### 3.4.3 Active Power Component

Power dissipation in CMOS devices is usually dominated by the dynamic power dissipation. Dynamic power consumption is frequency-dependent and is a function of the logic and the external I/O. Active power dissipation results from charging internal chip capacitances of the interconnect, unprogrammed antifuses, module inputs, and module outputs, plus external capacitances due to PC board traces and load device inputs. An additional component of the active power dissipation is the totem pole current in the CMOS transistor pairs. The net effect can be associated with an equivalent capacitance that can be combined with frequency and voltage to represent active power dissipation.

The power dissipated by a CMOS circuit can be expressed by the equation:

$$Power(\mu W) = C_{EQ} * V_{CCA}^2 * F(1)$$

EQ 2

where:

- $C_{EQ}$  = Equivalent capacitance expressed in picofarads (pF)

reliability. Devices should not be operated outside the recommended operating conditions.

**Table 21 • Recommended Operating Conditions**

| Parameter          | Commercial   | Industrial | Military    | Units |
|--------------------|--------------|------------|-------------|-------|
| Temperature Range* | 0 to +70     | –40 to +85 | –55 to +125 | °C    |
| VCCA               | 4.75 to 5.25 | 4.5 to 5.5 | 4.5 to 5.5  | V     |
| VCCI               | 3.14 to 3.47 | 3.0 to 3.6 | 3.0 to 3.6  | V     |

**Note:** \*Ambient temperature ( $T_A$ ) is used for commercial and industrial grades; case temperature ( $T_C$ ) is used for military grades.

approximately a 3 ns to a 6 ns delay, which is represented statistically in higher fanout (FO=8) routing delays in the data sheet specifications section, shown in Table 34, page 41.

### 3.11.3 Timing Derating

MX devices are manufactured with a CMOS process. Therefore, device performance varies according to temperature, voltage, and process changes. Minimum timing parameters reflect maximum operating voltage, minimum operating temperature and best-case processing. Maximum timing parameters reflect minimum operating voltage, maximum operating temperature and worst-case processing.

### 3.11.4 Temperature and Voltage Derating Factors

The following tables and figures show temperature and voltage derating factors for 40MX and 42MX FPGAs.

**Table 28 • 42MX Temperature and Voltage Derating Factors (Normalized to  $T_J = 25^\circ\text{C}$ ,  $V_{CCA} = 5.0\text{ V}$ )**

| 42MX Voltage | Temperature         |                     |                   |                    |                    |                    |                     |
|--------------|---------------------|---------------------|-------------------|--------------------|--------------------|--------------------|---------------------|
|              | $-55^\circ\text{C}$ | $-40^\circ\text{C}$ | $0^\circ\text{C}$ | $25^\circ\text{C}$ | $70^\circ\text{C}$ | $85^\circ\text{C}$ | $125^\circ\text{C}$ |
| 4.50         | 0.93                | 0.95                | 1.05              | 1.09               | 1.25               | 1.29               | 1.41                |
| 4.75         | 0.88                | 0.90                | 1.00              | 1.03               | 1.18               | 1.22               | 1.34                |
| 5.00         | 0.85                | 0.87                | 0.96              | 1.00               | 1.15               | 1.18               | 1.29                |
| 5.25         | 0.84                | 0.86                | 0.95              | 0.97               | 1.12               | 1.14               | 1.28                |
| 5.50         | 0.83                | 0.85                | 0.94              | 0.96               | 1.10               | 1.13               | 1.26                |

1. Routing delays are for typical designs across worst-case operating conditions. These parameters should be used for estimating device performance. Post-route timing analysis or simulation is required to determine actual performance.
2. Set-up times assume fanout of 3. Further testing information can be obtained from the Timer utility.
3. The hold time for the DFME1A macro may be greater than 0 ns. Use the Timer tool from the Designer software to check the hold time for this macro
4. Delays based on 35 pF loading
