

Welcome to [E-XFL.COM](#)

Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Active
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	-
Number of I/O	83
Number of Gates	24000
Voltage - Supply	3V ~ 3.6V, 4.5V ~ 5.5V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 85°C (TA)
Package / Case	100-BQFP
Supplier Device Package	100-PQFP (20x14)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/a42mx16-1pqg100i

Note: *QCLK1IN, QCLK2IN, QCLK3IN, and QCLK4IN are internally-generated signals.

3.2.5 MultiPlex I/O Modules

42MX devices feature Multiplex I/Os and support 5.0 V, 3.3 V, and mixed 3.3 V/5.0 V operations.

The MultiPlex I/O modules provide the interface between the device pins and the logic array. Figure 10, page 12 is a block diagram of the 42MX I/O module. A variety of user functions, determined by a library macro selection, can be implemented in the module. (See the *Antifuse Macro Library Guide* for more information.) All 42MX I/O modules contain tristate buffers, with input and output latches that can be configured for input, output, or bidirectional operation.

All 42MX devices contain flexible I/O structures, where each output pin has a dedicated output-enable control (Figure 10, page 12). The I/O module can be used to latch input or output data, or both, providing fast set-up time. In addition, the Designer software tools can build a D-type flip-flop using a C-module combined with an I/O module to register input and output signals. See the *Antifuse Macro Library Guide* for more details.

A42MX24 and A42MX36 devices also offer selectable PCI output drives, enabling 100% compliance with version 2.1 of the PCI specification. For low-power systems, all inputs and outputs are turned off to reduce current consumption to below 500 μ A.

To achieve 5.0 V or 3.3 V PCI-compliant output drives on A42MX24 and A42MX36 devices, a chip-wide PCI fuse is programmed via the Device Selection Wizard in the Designer software (Figure 11, page 12). When the PCI fuse is not programmed, the output drive is standard.

Silicon Sculptor programs devices independently to achieve the fastest programming times possible. After being programmed, each fuse is verified to insure that it has been programmed correctly. Furthermore, at the end of programming, there are integrity tests that are run to ensure no extra fuses have been programmed. Not only does it test fuses (both programmed and non-programmed), Silicon Sculptor also allows self-test to verify its own hardware extensively.

The procedure for programming an MX device using Silicon Sculptor is as follows:

1. Load the *.AFM file
2. Select the device to be programmed
3. Begin programming

When the design is ready to go to production, Microsemi offers device volume-programming services either through distribution partners or via In-House Programming from the factory.

For more details on programming MX devices, see the *AC225: Programming Antifuse Devices* application note and the *Silicon Sculptor 3 Programmers User Guide*.

3.3.4 Power Supply

MX devices are designed to operate in both 5.0V and 3.3V environments. In particular, 42MX devices can operate in mixed 5.0 V/3.3 V systems. The following table describes the voltage support of MX devices.

Table 6 • Voltage Support of MX Devices

Device	VCC	VCCA	VCCI	Maximum Input Tolerance	Nominal Output Voltage
40MX	5.0 V	—	—	5.5 V	5.0 V
	3.3 V	—	—	3.6 V	3.3 V
42MX	—	5.0 V	5.0 V	5.5 V	5.0 V
	—	3.3 V	3.3 V	3.6 V	3.3 V
	—	5.0 V	3.3 V	5.5 V	3.3 V

For A42MX24 and A42MX36 devices the VCCA supply has to be monotonic during power up in order for the POR to issue reset to the JTAG state machine correctly. For more information, see the *AC291: 42MX Family Devices Power-Up Behavior*.

3.3.5 Power-Up/Down in Mixed-Voltage Mode

When powering up 42MX in mixed voltage mode (VCCA = 5.0 V and VCCI = 3.3 V), VCCA must be greater than or equal to VCCI throughout the power-up sequence. If VCCI exceeds VCCA during power-up, one of two things will happen:

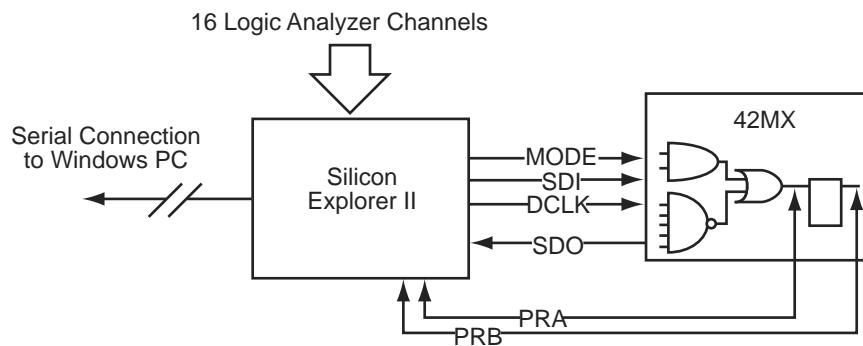

- The input protection diode on the I/Os will be forward biased
- The I/Os will be at logical High

In either case, ICC rises to high levels. For power-down, any sequence with VCCA and VCCI can be implemented.

3.3.6 Transient Current

Due to the simultaneous random logic switching activity during power-up, a transient current may appear on the core supply (VCC). Customers must use a regulator for the VCC supply that can source a minimum of 100 mA for transient current during power-up. Failure to provide enough power can prevent the system from powering up properly and result in functional failure. However, there are no reliability concerns, since transient current is distributed across the die instead of confined to a localized spot.

Since the transient current is not due to I/O switching, its value and duration are independent of the VCCI.

Figure 13 • Silicon Explorer II Setup with 42MX**Table 8 • Device Configuration Options for Probe Capability**

Security Fuse(s) Programmed	Mode	PRA, PRB ¹	SDI, SDO, DCLK ¹
No	LOW	User I/Os ²	User I/Os ²
No	HIGH	Probe Circuit Outputs	Probe Circuit Inputs
Yes	—	Probe Circuit Secured	Probe Circuit Secured

1. Avoid using SDI, SDO, DCLK, PRA and PRB pins as input or bidirectional ports. Since these pins are active during probing, input signals will not pass through these pins and may cause contention.
2. If no user signal is assigned to these pins, they will behave as unused I/Os in this mode. See the Pin Descriptions, page 83 for information on unused I/O pins

3.4.7 Design Consideration

It is recommended to use a series 70Ω termination resistor on every probe connector (SDI, SDO, MODE, DCLK, PRA and PRB). The 70Ω series termination is used to prevent data transmission corruption during probing and reading back the checksum.

3.4.8 IEEE Standard 1149.1 Boundary Scan Test (BST) Circuitry

42MX24 and 42MX36 devices are compatible with IEEE Standard 1149.1 (informally known as Joint Testing Action Group Standard or JTAG), which defines a set of hardware architecture and mechanisms for cost-effective board-level testing. The basic MX boundary-scan logic circuit is composed of the TAP (test access port), TAP controller, test data registers and instruction register (Figure 14, page 18). This circuit supports all mandatory IEEE 1149.1 instructions (EXTEST, SAMPLE/PRELOAD and BYPASS) and some optional instructions. Table 9, page 18 describes the ports that control JTAG testing, while Table 10, page 18 describes the test instructions supported by these MX devices.

Each test section is accessed through the TAP, which has four associated pins: TCK (test clock input), TDI and TDO (test data input and output), and TMS (test mode selector).

The TAP controller is a four-bit state machine. The '1's and '0's represent the values that must be present at TMS at a rising edge of TCK for the given state transition to occur. IR and DR indicate that the instruction register or the data register is operating in that state.

The TAP controller receives two control inputs (TMS and TCK) and generates control and clock signals for the rest of the test logic architecture. On power-up, the TAP controller enters the Test-Logic-Reset state. To guarantee a reset of the controller from any of the possible states, TMS must remain high for five TCK cycles.

42MX24 and 42MX36 devices support three types of test data registers: bypass, device identification, and boundary scan. The bypass register is selected when no other register needs to be accessed in a device. This speeds up test data transfer to other devices in a test data path. The 32-bit device identification register is a shift register with four fields (lowest significant byte (LSB), ID number, part number and version). The boundary-scan register observes and controls the state of each I/O pin.

Additionally, the back-annotation flow is compatible with all the major simulators and the simulation results can be cross-probed with Silicon Explorer II, Microsemi's integrated verification and logic analysis tool. Another tool included in the Libero software is the SmartGen macro builder, which easily creates popular and commonly used logic functions for implementation into your schematic or HDL design.

Microsemi's Libero software is compatible with the most popular FPGA design entry and verification tools from companies such as Mentor Graphics, Synopsys, and Cadence design systems.

See the Libero IDE web content at www.microsemi.com/soc/products/software/libero/default.aspx for further information on licensing and current operating system support.
