Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

3.2.3.3 Antifuse Structures

An antifuse is a “normally open” structure. The use of antifuses to implement a programmable logic device results in highly testable structures as well as efficient programming algorithms. There are no pre-existing connections; temporary connections can be made using pass transistors. These temporary connections can isolate individual antifuses to be programmed and individual circuit structures to be tested, which can be done before and after programming. For instance, all metal tracks can be tested for continuity and shorts between adjacent tracks, and the functionality of all logic modules can be verified.

Figure 7 • MX Routing Structure

3.2.4 Clock Networks

The 40MX devices have one global clock distribution network (CLK). A signal can be put on the CLK network by being routed through the CLKBUF buffer.

In 42MX devices, there are two low-skew, high-fanout clock distribution networks, referred to as CLKA and CLKB. Each network has a clock module (CLKMOD) that can select the source of the clock signal from any of the following (Figure 8, page 11):

- Externally from the CLKA pad, using CLKBUF buffer
- Externally from the CLKB pad, using CLKBUF buffer
- Internally from the CLKINTA input, using CLKINT buffer
- Internally from the CLKINTB input, using CLKINT buffer

The clock modules are located in the top row of I/O modules. Clock drivers and a dedicated horizontal clock track are located in each horizontal routing channel.

Clock input pads in both 40MX and 42MX devices can also be used as normal I/Os, bypassing the clock networks.

The A42MX36 device has four additional register control resources, called quadrant clock networks (Figure 9, page 11). Each quadrant clock provides a local, high-fanout resource to the contiguous logic modules within its quadrant of the device. Quadrant clock signals can originate from specific I/O pins or from the internal array and can be used as a secondary register clock, register clear, or output enable.

reliability. Devices should not be operated outside the recommended operating conditions.

t_H	Input Hold to CLK	0	–	0	–	0	–	ns

1. TOFF is system dependent. MX PCI devices have 7.4 ns turn-off time, reflection is typically an additional 10 ns.
 2. REQ# and GNT# are point-to-point signals and have different output valid delay and input setup times than do bussed signals. GNT# has a setup of 10; REW# has a setup of 12.
