Understanding Embedded - Microprocessors

Embedded microprocessors are specialized computing chips designed to perform specific tasks within an embedded system. Unlike general-purpose microprocessors found in personal computers, embedded microprocessors are tailored for dedicated functions within larger systems, offering optimized performance, efficiency, and reliability. These microprocessors are integral to the operation of countless electronic devices, providing the computational power necessary for controlling processes, handling data, and managing communications.

Applications of Embedded - Microprocessors

Embedded microprocessors are utilized across a broad spectrum of applications, making them indispensable in

3 Electrical and Thermal Characteristics

This section provides the AC and DC electrical specifications and thermal characteristics for the MPC850. Table 2 provides the maximum ratings.

Table 2. Maximum Ratings

(GND = 0V)

Rating	Symbol	Value	Unit
Supply voltage	VDDH	-0.3 to 4.0	V
	VDDL	-0.3 to 4.0	V
	KAPWR	-0.3 to 4.0	V
	VDDSYN	-0.3 to 4.0	V
Input voltage [1]	V_{in}	GND-0.3 to VDDH + 2.5 V	V
Junction temperature [2]	T_j	0 to 95 (standard) -40 to 95 (extended)	°C
Storage temperature range	T_{stg}	-55 to +150	°C

1 Functional operating conditions are provided with the DC electrical specifications in Table 5. Absolute maximum ratings are stress ratings only; functional operation at the maxima is not guaranteed. Stress beyond those listed may affect device reliability or cause permanent damage to the device.
CAUTION: All inputs that tolerate 5 V cannot be more than 2.5 V greater than the supply voltage. This restriction applies to power-up and normal operation (that is, if the MPC850 is unpowered, voltage greater than 2.5 V must not be applied to its inputs).

2 The MPC850, a high-frequency device in a BGA package, does not provide a guaranteed maximum ambient temperature. Only maximum junction temperature is guaranteed. It is the responsibility of the user to consider power dissipation and thermal management. Junction temperature ratings are the same regardless of frequency rating of the device.

This device contains circuitry protecting against damage due to high-static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (for example, either GND or V_{CC}). Table 3 provides the package thermal characteristics for the MPC850.

1 The minima provided assume a 0 pF load, whereas maxima assume a 50pF load. For frequencies not marked on the part, new bus timing must be calculated for all frequency-dependent AC parameters. Frequency-dependent AC parameters are those with an entry in the FFactor column. AC parameters without an FFactor entry do not need to be calculated and can be taken directly from the frequency column corresponding to the frequency marked on the part. The following equations should be used in these calculations.

For a frequency F, the following equations should be applied to each one of the above parameters:

For minima:

$$D = \frac{FFACTOR \times 1000}{F} + (D_{50} - 20 \times FFACTOR)$$

For maxima:

$$D = \frac{FFACTOR \times 1000}{F} + (D_{50} - 20 \times FFACTOR) + 1ns(CAP\ LOAD - 50) / 10$$

where:

D is the parameter value to the frequency required in ns

F is the operation frequency in MHz

D_{50} is the parameter value defined for 50 MHz

CAP LOAD is the capacitance load on the signal in question.

FFACTOR is the one defined for each of the parameters in the table.

2 Phase and frequency jitter performance results are valid only if the input jitter is less than the prescribed value.

3 If the rate of change of the frequency of EXTAL is slow (i.e. it does not jump between the minimum and maximum values in one cycle) or the frequency of the jitter is fast (i.e., it does not stay at an extreme value for a long time) then the maximum allowed jitter on EXTAL can be up to 2%.

4 The timing for $\overline{BR}$ output is relevant when the MPC850 is selected to work with external bus arbiter. The timing for $\overline{BG}$ output is relevant when the MPC850 is selected to work with internal bus arbiter.

5 The setup times required for $\overline{TA}$, $\overline{TEA}$, and $\overline{BI}$ are relevant only when they are supplied by an external device (and not when the memory controller or the PCMCIA interface drives them).

6 The timing required for $\overline{BR}$ input is relevant when the MPC850 is selected to work with the internal bus arbiter. The timing for $\overline{BG}$ input is relevant when the MPC850 is selected to work with the external bus arbiter.

7 The D[0–31] and DP[0–3] input timings B20 and B21 refer to the rising edge of the CLKOUT in which the $\overline{TA}$ input signal is asserted.

8 The D[0:31] and DP[0:3] input timings B20 and B21 refer to the falling edge of CLKOUT. This timing is valid only for read accesses controlled by chip-selects controlled by the UPM in the memory controller, for data beats where DLT3 = 1 in the UPM RAM words. (This is only the case where data is latched on the falling edge of CLKOUT.

9 The timing B30 refers to $\overline{CS}$ when ACS = '00' and to $\overline{WE[0:3]}$ when CSNT = '0'.

10 The signal UPWAIT is considered asynchronous to CLKOUT and synchronized internally. The timings specified in B37 and B38 are specified to enable the freeze of the UPM output signals.

11 The $\overline{AS}$ signal is considered asynchronous to CLKOUT.

The timings I41, I42, and I43 are specified to allow the correct function of the $\overline{\text{IRQ}}$ lines detection circuitry, and has no direct relation with the total system interrupt latency that the MPC850 is able to support
