
Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Obsolete
Number of LABs/CLBs	1664
Number of Logic Elements/Cells	16640
Total RAM Bits	212992
Number of I/O	502
Number of Gates	1052000
Voltage - Supply	2.375V ~ 2.625V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 85°C (TJ)
Package / Case	652-BGA
Supplier Device Package	652-BGA (45x45)
Purchase URL	https://www.e-xfl.com/product-detail/intel/ep20k400bc652-3

All APEX 20K devices are reconfigurable and are 100% tested prior to shipment. As a result, test vectors do not have to be generated for fault coverage purposes. Instead, the designer can focus on simulation and design verification. In addition, the designer does not need to manage inventories of different application-specific integrated circuit (ASIC) designs; APEX 20K devices can be configured on the board for the specific functionality required.

APEX 20K devices are configured at system power-up with data stored in an Altera serial configuration device or provided by a system controller. Altera offers in-system programmability (ISP)-capable EPC1, EPC2, and EPC16 configuration devices, which configure APEX 20K devices via a serial data stream. Moreover, APEX 20K devices contain an optimized interface that permits microprocessors to configure APEX 20K devices serially or in parallel, and synchronously or asynchronously. The interface also enables microprocessors to treat APEX 20K devices as memory and configure the device by writing to a virtual memory location, making reconfiguration easy.

After an APEX 20K device has been configured, it can be reconfigured in-circuit by resetting the device and loading new data. Real-time changes can be made during system operation, enabling innovative reconfigurable computing applications.

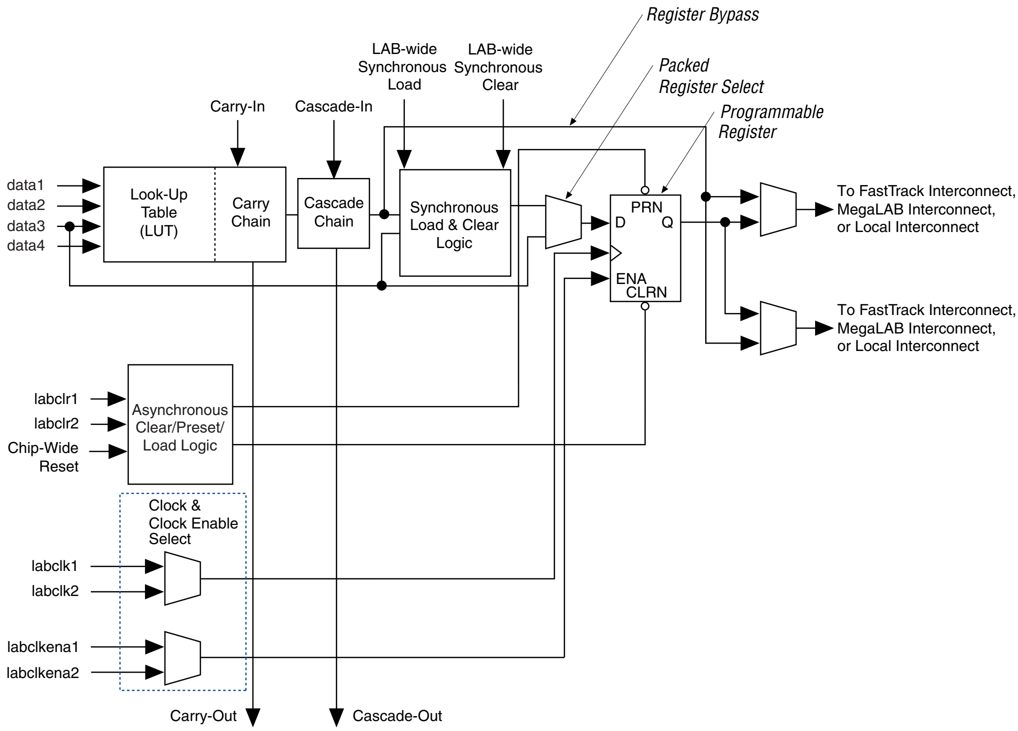
APEX 20K devices are supported by the Altera Quartus II development system, a single, integrated package that offers HDL and schematic design entry, compilation and logic synthesis, full simulation and worst-case timing analysis, SignalTap logic analysis, and device configuration. The Quartus II software runs on Windows-based PCs, Sun SPARCstations, and HP 9000 Series 700/800 workstations.

The Quartus II software provides NativeLink interfaces to other industry-standard PC- and UNIX workstation-based EDA tools. For example, designers can invoke the Quartus II software from within third-party design tools. Further, the Quartus II software contains built-in optimized synthesis libraries; synthesis tools can use these libraries to optimize designs for APEX 20K devices. For example, the Synopsys Design Compiler library, supplied with the Quartus II development system, includes DesignWare functions optimized for the APEX 20K architecture.

Logic Element

The LE, the smallest unit of logic in the APEX 20K architecture, is compact and provides efficient logic usage. Each LE contains a four-input LUT, which is a function generator that can quickly implement any function of four variables. In addition, each LE contains a programmable register and carry and cascade chains. Each LE drives the local interconnect, MegaLAB interconnect, and FastTrack Interconnect routing structures. See Figure 5.

Figure 5. APEX 20K Logic Element



Each LE's programmable register can be configured for D, T, JK, or SR operation. The register's clock and clear control signals can be driven by global signals, general-purpose I/O pins, or any internal logic. For combinatorial functions, the register is bypassed and the output of the LUT drives the outputs of the LE.

Figure 10. FastTrack Connection to Local Interconnect

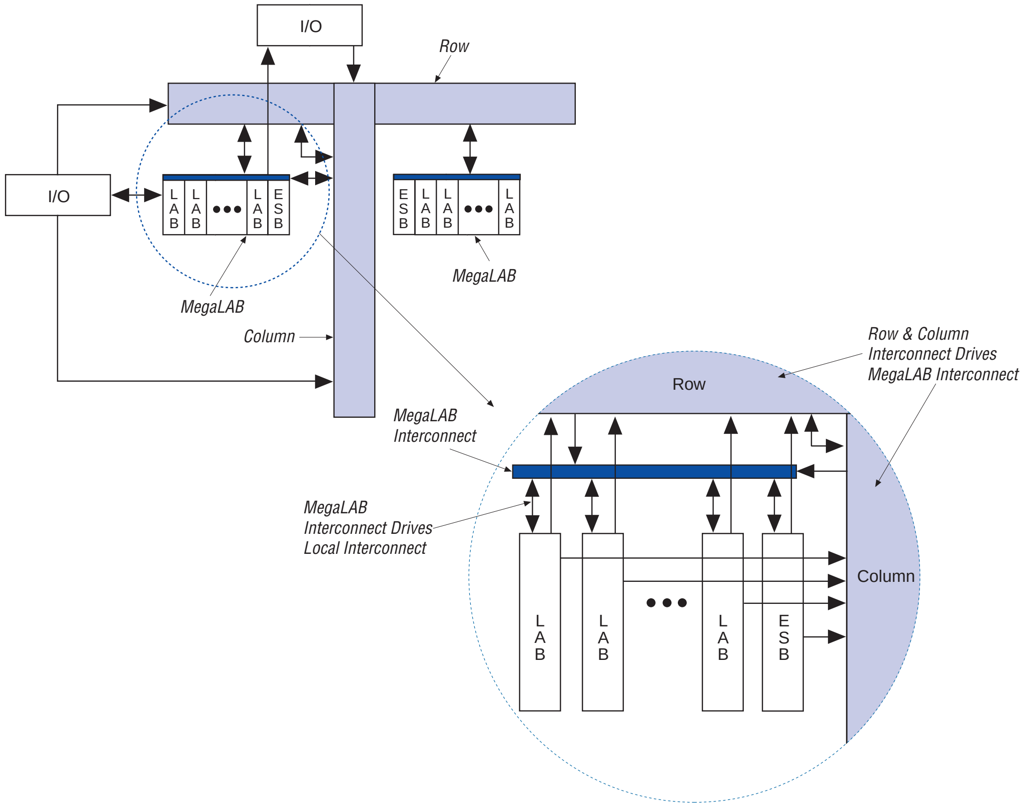


Figure 14. APEX 20K Macrocell

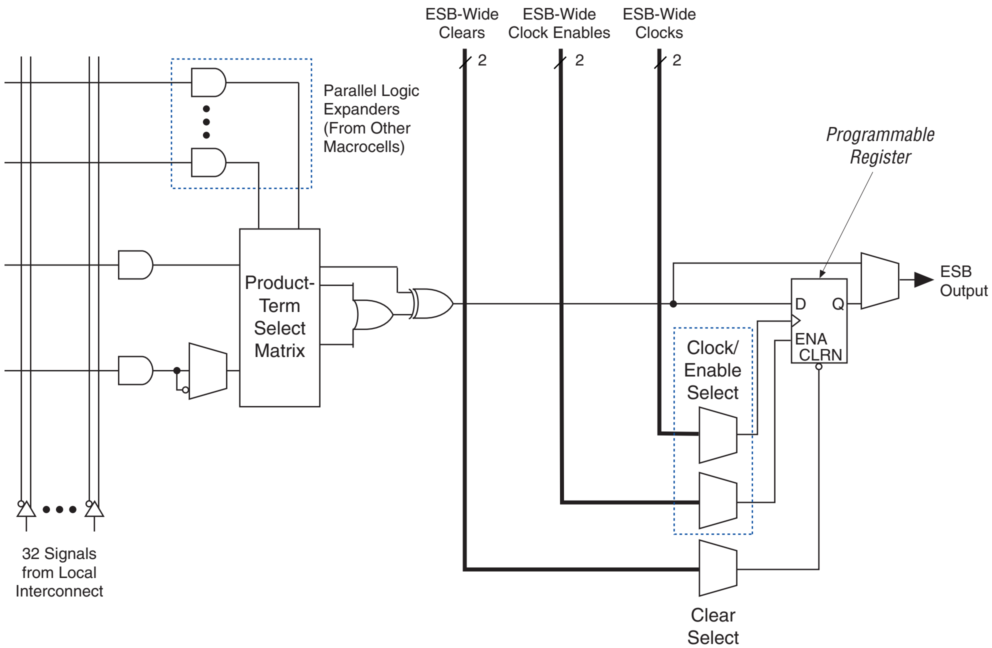


For registered functions, each macrocell register can be programmed individually to implement D, T, JK, or SR operation with programmable clock control. The register can be bypassed for combinatorial operation. During design entry, the designer specifies the desired register type; the Quartus II software then selects the most efficient register operation for each registered function to optimize resource utilization. The Quartus II software or other synthesis tools can also select the most efficient register operation automatically when synthesizing HDL designs.

Each programmable register can be clocked by one of two ESB-wide clocks. The ESB-wide clocks can be generated from device dedicated clock pins, global signals, or local interconnect. Each clock also has an associated clock enable, generated from the local interconnect. The clock and clock enable signals are related for a particular ESB; any macrocell using a clock also uses the associated clock enable.

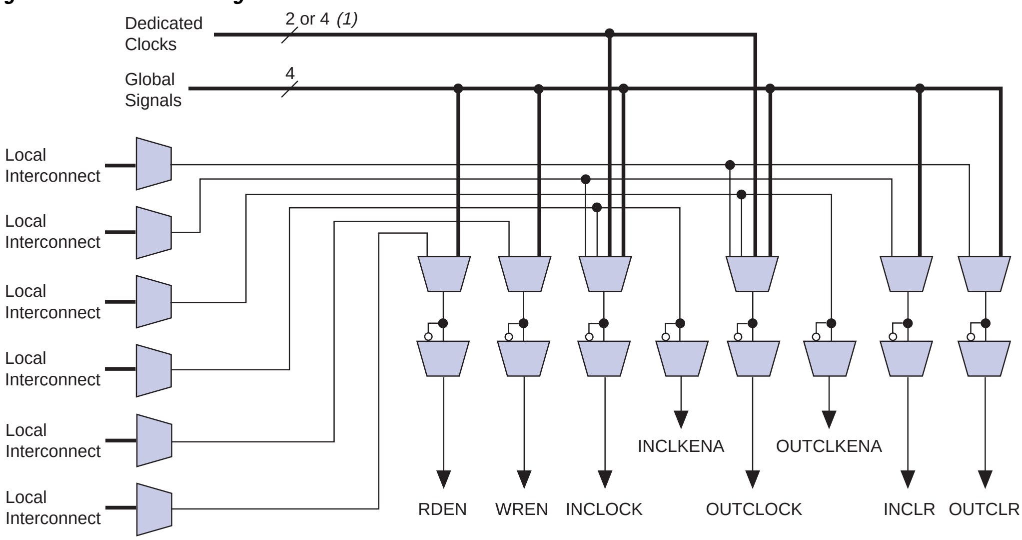
If both the rising and falling edges of a clock are used in an ESB, both ESB-wide clock signals are used.

For more information on APEX 20KE devices and CAM, see *Application Note 119 (Implementing High-Speed Search Applications with APEX CAM).*

Driving Signals to the ESB

ESBs provide flexible options for driving control signals. Different clocks can be used for the ESB inputs and outputs. Registers can be inserted independently on the data input, data output, read address, write address, WE, and RE signals. The global signals and the local interconnect can drive the WE and RE signals. The global signals, dedicated clock pins, and local interconnect can drive the ESB clock signals. Because the LEs drive the local interconnect, the LEs can control the WE and RE signals and the ESB clock, clock enable, and asynchronous clear signals. Figure 24 shows the ESB control signal generation logic.

Figure 24. ESB Control Signal Generation



Note to Figure 24:
(1) APEX 20KE devices have four dedicated clocks.

An ESB is fed by the local interconnect, which is driven by adjacent LEs (for high-speed connection to the ESB) or the MegaLAB interconnect. The ESB can drive the local, MegaLAB, or FastTrack Interconnect routing structure to drive LEs and IOEs in the same MegaLAB structure or anywhere in the device.

Implementing Logic in ROM

In addition to implementing logic with product terms, the ESB can implement logic functions when it is programmed with a read-only pattern during configuration, creating a large LUT. With LUTs, combinatorial functions are implemented by looking up the results, rather than by computing them. This implementation of combinatorial functions can be faster than using algorithms implemented in general logic, a performance advantage that is further enhanced by the fast access times of ESBs. The large capacity of ESBs enables designers to implement complex functions in one logic level without the routing delays associated with linked LEs or distributed RAM blocks. Parameterized functions such as LPM functions can take advantage of the ESB automatically. Further, the Quartus II software can implement portions of a design with ESBs where appropriate.

Programmable Speed/Power Control

APEX 20K ESBs offer a high-speed mode that supports very fast operation on an ESB-by-ESB basis. When high speed is not required, this feature can be turned off to reduce the ESB's power dissipation by up to 50%. ESBs that run at low power incur a nominal timing delay adder. This Turbo Bit™ option is available for ESBs that implement product-term logic or memory functions. An ESB that is not used will be powered down so that it does not consume DC current.

Designers can program each ESB in the APEX 20K device for either high-speed or low-power operation. As a result, speed-critical paths in the design can run at high speed, while the remaining paths operate at reduced power.

I/O Structure

The APEX 20K IOE contains a bidirectional I/O buffer and a register that can be used either as an input register for external data requiring fast setup times, or as an output register for data requiring fast clock-to-output performance. IOEs can be used as input, output, or bidirectional pins. For fast bidirectional I/O timing, LE registers using local routing can improve setup times and OE timing. The Quartus II software Compiler uses the programmable inversion option to invert signals from the row and column interconnect automatically where appropriate. Because the APEX 20K IOE offers one output enable per pin, the Quartus II software Compiler can emulate open-drain operation efficiently.

The APEX 20K IOE includes programmable delays that can be activated to ensure zero hold times, minimum clock-to-output times, input IOE register-to-core register transfers, or core-to-output IOE register transfers. A path in which a pin directly drives a register may require the delay to ensure zero hold time, whereas a path in which a pin drives a register through combinatorial logic may not require the delay.

Advanced I/O Standard Support

APEX 20KE IOEs support the following I/O standards: LVTTL, LVCMOS, 1.8-V I/O, 2.5-V I/O, 3.3-V PCI, PCI-X, 3.3-V AGP, LVDS, LVPECL, GTL+, CTT, HSTL Class I, SSTL-3 Class I and II, and SSTL-2 Class I and II.

For more information on I/O standards supported by APEX 20KE devices, see *Application Note 117 (Using Selectable I/O Standards in Altera Devices)*.

The APEX 20KE device contains eight I/O banks. In QFP packages, the banks are linked to form four I/O banks. The I/O banks directly support all standards except LVDS and LVPECL. All I/O banks can support LVDS and LVPECL with the addition of external resistors. In addition, one block within a bank contains circuitry to support high-speed True-LVDS and LVPECL inputs, and another block within a particular bank supports high-speed True-LVDS and LVPECL outputs. The LVDS blocks support all of the I/O standards. Each I/O bank has its own `VCCIO` pins. A single device can support 1.8-V, 2.5-V, and 3.3-V interfaces; each bank can support a different standard independently. Each bank can also use a separate V_{REF} level so that each bank can support any of the terminated standards (such as SSTL-3) independently. Within a bank, any one of the terminated standards can be supported. EP20K300E and larger APEX 20KE devices support the LVDS interface for data pins (smaller devices support LVDS clock pins, but not data pins). All EP20K300E and larger devices support the LVDS interface for data pins up to 155 Mbit per channel; EP20K400E devices and larger with an X-suffix on the ordering code add a serializer/deserializer circuit and PLL for higher-speed support.

Each bank can support multiple standards with the same `VCCIO` for output pins. Each bank can support one voltage-referenced I/O standard, but it can support multiple I/O standards with the same `VCCIO` voltage level. For example, when `VCCIO` is 3.3 V, a bank can support LVTTL, LVCMOS, 3.3-V PCI, and SSTL-3 for inputs and outputs.

When the LVDS banks are not used as LVDS I/O banks, they support all of the other I/O standards. Figure 29 shows the arrangement of the APEX 20KE I/O banks.

Note to Tables 32 and 33:
(1) These timing parameters are sample-tested only.

Tables 34 through 37 show APEX 20KE LE, ESB, routing, and functional timing microparameters for the f_{MAX} timing model.

Table 34. APEX 20KE LE Timing Microparameters

Symbol	Parameter
t_{SU}	LE register setup time before clock
t_H	LE register hold time after clock
t_{CO}	LE register clock-to-output delay
t_{LUT}	LUT delay for data-in to data-out

Table 35. APEX 20KE ESB Timing Microparameters

Symbol	Parameter
t_{ESBARC}	ESB Asynchronous read cycle time
t_{ESBSRC}	ESB Synchronous read cycle time
t_{ESBAWC}	ESB Asynchronous write cycle time
t_{ESBSWC}	ESB Synchronous write cycle time
$t_{ESBWASU}$	ESB write address setup time with respect to WE
t_{ESBWAH}	ESB write address hold time with respect to WE
$t_{ESBWDSU}$	ESB data setup time with respect to WE
t_{ESBWDH}	ESB data hold time with respect to WE
$t_{ESBRASU}$	ESB read address setup time with respect to RE
t_{ESBRAH}	ESB read address hold time with respect to RE
$t_{ESBWESU}$	ESB WE setup time before clock when using input register
t_{ESBWEH}	ESB WE hold time after clock when using input register
$t_{ESBDATASU}$	ESB data setup time before clock when using input register
$t_{ESBDATAH}$	ESB data hold time after clock when using input register
$t_{ESBWADDRSU}$	ESB write address setup time before clock when using input registers
$t_{ESBRADDRSU}$	ESB read address setup time before clock when using input registers
$t_{ESBDATACO1}$	ESB clock-to-output delay when using output registers
$t_{ESBDATACO2}$	ESB clock-to-output delay without output registers
t_{ESBDD}	ESB data-in to data-out delay for RAM mode
t_{PD}	ESB Macrocell input to non-registered output
$t_{PTERMSU}$	ESB Macrocell register setup time before clock
$t_{PTERMCO}$	ESB Macrocell register clock-to-output delay

Power Consumption

To estimate device power consumption, use the interactive power calculator on the Altera web site at **http://www.altera.com**.

Configuration & Operation

The APEX 20K architecture supports several configuration schemes. This section summarizes the device operating modes and available device configuration schemes.

Operating Modes

The APEX architecture uses SRAM configuration elements that require configuration data to be loaded each time the circuit powers up. The process of physically loading the SRAM data into the device is called configuration. During initialization, which occurs immediately after configuration, the device resets registers, enables I/O pins, and begins to operate as a logic device. The I/O pins are tri-stated during power-up, and before and during configuration. Together, the configuration and initialization processes are called *command mode*; normal device operation is called *user mode*.

Before and during device configuration, all I/O pins are pulled to V_{CCIO} by a built-in weak pull-up resistor.
