What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Note: Note the following regarding pin names. For details, see section 1.5, Pin Assignments.

- We recommend using pins that have a letter ("‐A", "‐B", etc.) to indicate group membership appended to their names as groups.
For the RSPI, QSPI, SDHI, and MMC interfaces, the AC portion of the electrical characteristics is measured for each group.
- Pins that have "‐DS" appended to their names can be used as triggers for release from deep software standby.
- RIIC pin functions that have [FM+] appended to their names support fast-mode plus.

Note 1. Supply current values are with all output pins unloaded and all input pull-up MOSs in the off state.

Note 2. Supply of the clock signal to peripheral modules is stopped in this state. This does not include operations as BGO (background operations).

Note 3. I_{CC} depends on f (I_{CLK}) as follows. ($I_{CLK}:P_{CLKA}:P_{CLKB}/P_{CLKC}/P_{CLKD}:B_{CLK}:B_{CLK} \text{ pin} = 10:5:2.5:5:2.5$ when $EXTAL = 24 \text{ MHz}$)

$$I_{CC} \text{ Typ.} = 0.09 \times f + 7 \text{ (normal operation in high-speed operating mode)}$$

$$I_{CC} \text{ Typ.} = 0.14 \times f + 74 \text{ (low-speed operating mode 1)}$$

$$I_{CC} \text{ Max.} = 0.50 \times f + 4 \text{ (sleep mode)}$$

Note 4. This does not include operations as BGO (background operations). Whether supply of the clock signal to peripheral modules continues or is stopped only depends on the state determined by the settings of the bits in module stop control registers A to D. The setting for the peripheral module clock stopped state is $F_{CLK} = B_{CLK} = P_{CLKA} = P_{CLKB} = P_{CLKC} = P_{CLKD} = B_{CLK} \text{ pin} = 3.75 \text{ MHz}$ (division by 64).

Note 1. Definition of reprogram/erase cycle:

The reprogram/erase cycle is the number of erasing for each block. When the reprogram/erase cycle is n times (n = 1000), erasing can be performed n times for each block. For instance, when 256-byte programming is performed 32 times for different addresses in 8-Kbyte block and then the entire block is erased, the reprogram/erase cycle is counted as one. However, programming the same address for several times as one erasing is not enabled (overwriting is prohibited).

Note 2. This is the minimum number of times to guarantee all the characteristics after reprogramming (guaranteed range is from 1 to the value of the minimum value).

Note 3. This shows the characteristics when reprogramming is performed within the specified range, including the minimum value.
