What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	dsPIC
Core Size	16-Bit Dual-Core
Speed	180MHz, 200MHz
Connectivity	I²C, IrDA, LINbus, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, DMA, Motor Control PWM, POR, PWM, QEI, WDT
Number of I/O	53
Program Memory Size	88KB (88K x 8)
Program Memory Type	FLASH, PRAM
EEPROM Size	-
RAM Size	20K x 8
Voltage - Supply (Vcc/Vdd)	3V ~ 3.6V
Data Converters	A/D 34x12b; D/A 4x12b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	64-VFQFN Exposed Pad
Supplier Device Package	64-QFN (9x9)

3.1.5 PROGRAMMER'S MODEL

The programmer's model for the dsPIC33CH128MP508 family is shown in Figure 3-2. All registers in the programmer's model are memory-mapped and can be manipulated directly by instructions. Table 3-1 lists a description of each register.

In addition to the registers contained in the programmer's model, the dsPIC33CH128MP508 devices contain control registers for Modulo Addressing, Bit-Reversed Addressing and interrupts. These registers are described in subsequent sections of this document.

All registers associated with the programmer's model are memory-mapped, as shown in Figure 3-3 and Figure 3-4.

TABLE 3-1: PROGRAMMER'S MODEL REGISTER DESCRIPTIONS

Register(s) Name	Description
W0 through W15(1)	Working Register Array
W0 through W14(1)	Alternate Working Register Array 1
W0 through W14(1)	Alternate Working Register Array 2
W0 through W14(1)	Alternate Working Register Array 3
W0 through W14(1)	Alternate Working Register Array 4
ACCA, ACCB	40-Bit DSP Accumulators (Additional 4 Alternate Accumulators)
PC	23-Bit Program Counter
SR	ALU and DSP Engine STATUS Register
SPLIM	Stack Pointer Limit Value Register
TBLPAG	Table Memory Page Address Register
DSRPAG	Extended Data Space (EDS) Read Page Register
RCOUNT	REPEAT Loop Counter Register
DCOUNT	DO Loop Counter Register
DOSTARTH, DOSTARTL(2)	DO Loop Start Address Register (High and Low)
DOENDH, DOENDL	DO Loop End Address Register (High and Low)
CORCON	Contains DSP Engine, DO Loop Control and Trap Status bits

Note 1: Memory-mapped W0 through W14 represent the value of the register in the currently active CPU context.

2: The DOSTARTH and DOSTARTL registers are read-only.

1 = Data transmitter has indicated that data is available to be read by data receiver in MSI1MBXnD (DTRDYx is automatically set by a data transmitter processor write to assigned MSI1MBXnD); Meaning when configured as a:
- Transmitter: Data is written. Waiting for receiver to read.
- Receiver: New data is ready to read.

0 = No data is available to be read by receiver in MSI1MBXnD (or the handshake protocol logic block is disabled)

5.3 Slave Processor Control

The MSI contains three control bits related to Slave processor control within the MSI1CON register.

5.3.1 SLAVE ENABLE (SLVEN) CONTROL

The SLVEN (MSI1CON<15>) control bit provides a means for the Master processor to enable or disable the Slave processor.

The Slave is disabled when SLVEN (MSI1CON<15>) = 0. In this state:

- The Slave is held in the Reset state
- The Master has access to the Slave PRAM (to load it out of a device Reset)
- The Slave Reset status bit, SLVRST (MSI1STAT<15>) = 1

The Slave is enabled when SLVEN (MSI1CON<15>) = 1. In this state:

- The Slave Reset is released and it will start to execute code in whatever mode it is configured to operate in
- The Master processor will no longer have access to the Slave PRAM
- The Slave Reset status bit, SLVRST (MSI1STAT<15>) = 0

Note: The SLVRST (MSI1STAT<15>) status bit indicates when the Slave is in Reset. The associated interrupt only occurs when the Slave enters the Reset state after having previously not been in Reset. That is, no interrupt can be generated until the Slave is first enabled.

The SLVEN bit may only be modified after satisfying the hardware write interlock. The SLVEN bit is protected from unexpected writes through a software unlocking sequence that is based on the MSI1KEY register. Given the critical nature of the MSI control interface, the MSI macro unlock mechanism is independent from that of the Flash controller for added robustness.

Completing a predefined data write sequence to the MSI1KEY register will open a window. The SLVEN bit should be written on the first instruction that follows the unlock sequence. No other bits within the MSI1CON register are affected by the interlock. The MSI1KEY register is not a physical register. A read of the MSI1KEY register will read all '0's.

When the SLVEN bit lock is enabled (i.e., the bits are locked and cannot be modified), the instruction sequence shown in Example 5-1 must be executed to open the lock. The unlock sequence is a prerequisite to both setting and clearing the target control bit.

Note: It is recommended to enable SRSTIE (MSI1CON<7>) = 1 prior to enabling the SLVEN bit. This will make the design robust and will update the Master with the Reset state of the Slave.

EXAMPLE 5-1: MSI ENABLE OPERATION

```
//Unlock Key to allow MSI Enable control
MOV.b   #0x55, W0
MOV.b   WREG, MSI1KEY
MOV.b   #0xAA, W0
MOV.b   WREG, MSI1KEY
// Enable MSI
BSET    MSI1CON, SLVEN
```

EXAMPLE 5-2: MSI ENABLE OPERATION IN C CODE

```
#include <libpic30.h>
_start_slave();
```

5.4 Slave Reset Coupling Control

In all operating modes, the user may couple or decouple the Master Run-Time Resets to the Slave Reset by using the Master Slave Reset Enable (S1MSRE) fuse. The Resets are effectively coupled by directing the selected Reset source to the SLVEN bit Reset.

In all operating modes, the user may also choose whether the SLVEN bit is reset or not in the event of a Slave Run-Time Reset by using the Slave Reset Enable (S1SSRE) fuse.

A user may choose to reset SLVEN in the event of a Slave Reset because that event could be an indicator of a problem with Slave execution. The Slave would be placed in Reset and the Master alerted (via the Slave Reset event interrupt, need to make SRSTIE (MSI1CON<7> = 1) to attempt to rectify the problem. The Master must re-enable the Slave by setting the SLVEN bit again.

Alternatively, the user may choose to not halt the Slave in the event of a Slave Reset, and just allow it to restart execution after a Reset and continue operation as soon as possible. The Slave Reset event interrupt would still occur, but could be ignored by the Master.
