Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Details

Product Status	Obsolete
Number of LABs/CLBs	160
Number of Logic Elements/Cells	1280
Total RAM Bits	65536
Number of I/O	72
Number of Gates	-
Voltage - Supply	1.14V ~ 1.26V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 70°C (TA)
Package / Case	100-TQFP
Supplier Device Package	100-VQFP (14x14)
Purchase URL	https://www.e-xfl.com/product-detail/lattice-semiconductor/ice65l01f-lvq100c

Overview

The Lattice Semiconductor iCE65 programmable logic family is specifically designed to deliver the lowest static and dynamic power consumption of any comparable CPLD or FPGA device. iCE65 devices are designed for cost-sensitive, high-volume applications and provide on-chip, nonvolatile configuration memory (NVCM) to customize for a specific application. iCE65 devices can self-configure from a configuration image stored in an external commodity SPI serial Flash PROM or be downloaded from an external processor over an SPI-like serial port.

The three iCE65 components, highlighted in [Table 1](#), deliver from approximately 1K to nearly 8K logic cells and flip-flops while consuming a fraction of the power of comparable programmable logic devices. Each iCE65 device includes between 16 to 32 RAM blocks, each with 4Kbits of storage, for on-chip data storage and data buffering.

As pictured in [Figure 1](#), each iCE65 device consists of four primary architectural elements.

- An array of Programmable Logic Blocks (PLBs)
 - ◆ Each PLB contains eight Logic Cells (LCs); each Logic Cell consists of ...
 - A fast, four-input look-up table (LUT4) capable of implementing any combinational logic function of up to four inputs, regardless of complexity
 - A 'D'-type flip-flop with an optional clock-enable and set/reset control
 - Fast carry logic to accelerate arithmetic functions such as adders, subtracters, comparators, and counters.
 - ◆ Common clock input with polarity control, clock-enable input, and optional set/reset control input to the PLB is shared among all eight Logic Cells
- Two-port, 4Kbit RAM blocks (RAM4K)
 - ◆ 256x16 default configuration; selectable data width using programmable logic resources
 - ◆ Simultaneous read and write access; ideal for FIFO memory and data buffering applications
 - ◆ RAM contents pre-loadable during configuration
- Four I/O banks with independent supply voltage, each with multiple Programmable Input/Output (PIO) blocks
 - ◆ LVCMOS I/O standards and LVDS outputs supported in all banks
 - ◆ I/O Bank 3 supports additional SSTL, MDDR, LVDS, and SubLVDS I/O standards
- Programmable interconnections between the blocks
 - ◆ Flexible connections between all programmable logic functions
 - ◆ Eight dedicated low-skew, high-fanout clock distribution networks

Programmable Logic Block (PLB)

Generally, a logic design for an iCE65 component is created using a high-level hardware description language such as Verilog or VHDL. The Lattice Semiconductor development software then synthesizes the high-level description into equivalent functions built using the programmable logic resources within each iCE65 device. Both sequential and combinational functions are constructed from an array of Programmable Logic Blocks (PLBs). Each PLB contains eight Logic Cells (LCs), as pictured in [Figure 4](#), and share common control inputs, such as clocks, reset, and enable controls.

PLBs are connected to one another and other logic functions using the rich Programmable Interconnect resources.

Logic Cell (LC)

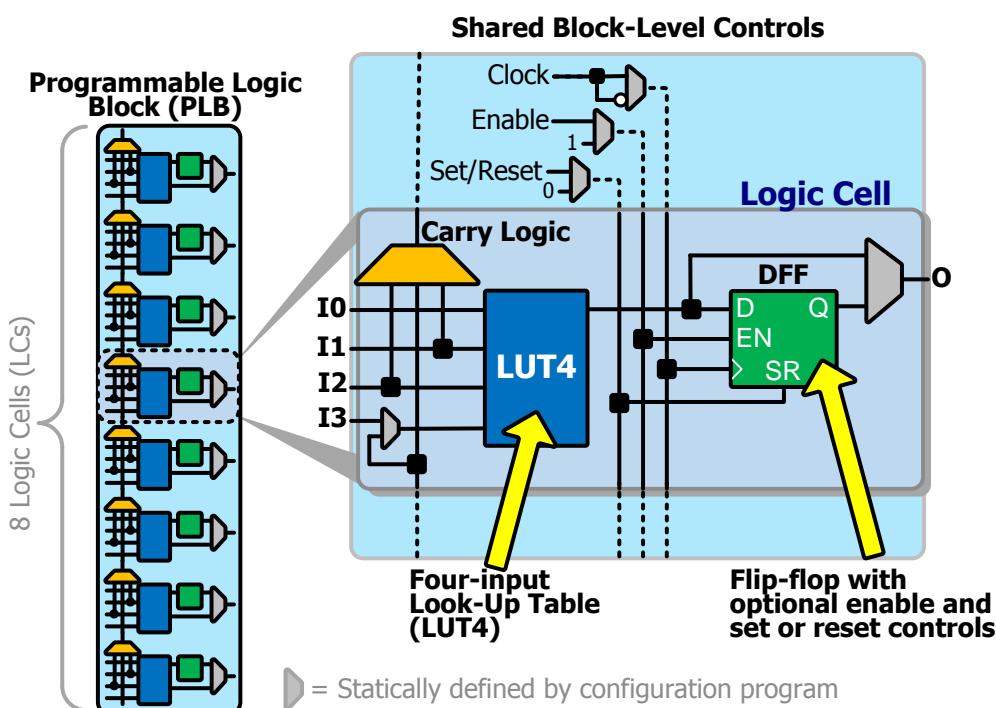

Each iCE65 device contains thousands of Logic Cells (LCs), as listed in [Table 1](#). Each Logic Cell includes three primary logic elements, shown in [Figure 4](#).

- A four-input [Look-Up Table \(LUT4\)](#) builds any combinational logic function, of any complexity, of up to four inputs. Similarly, the LUT4 element behaves as a 16x1 Read-Only Memory (ROM). Combine and cascade multiple LUT4s to create wider logic functions.

Figure 4: Programmable Logic Block and Logic Cell

- A [‘D’-style Flip-Flop \(DFF\)](#), with an optional clock-enable and reset control input, builds sequential logic functions. Each DFF also connects to a global reset signal that is automatically asserted immediately following device configuration.
- [Carry Logic](#) boosts the logic efficiency and performance of arithmetic functions, including adders, subtracters, comparators, binary counters and some wide, cascaded logic functions.

The output from a Logic Cell is available to all inputs to all eight Logic Cells within the Programmable Logic Block. Similarly, the Logic Cell output feeds into fabric to connect to other features on the iCE65 device.

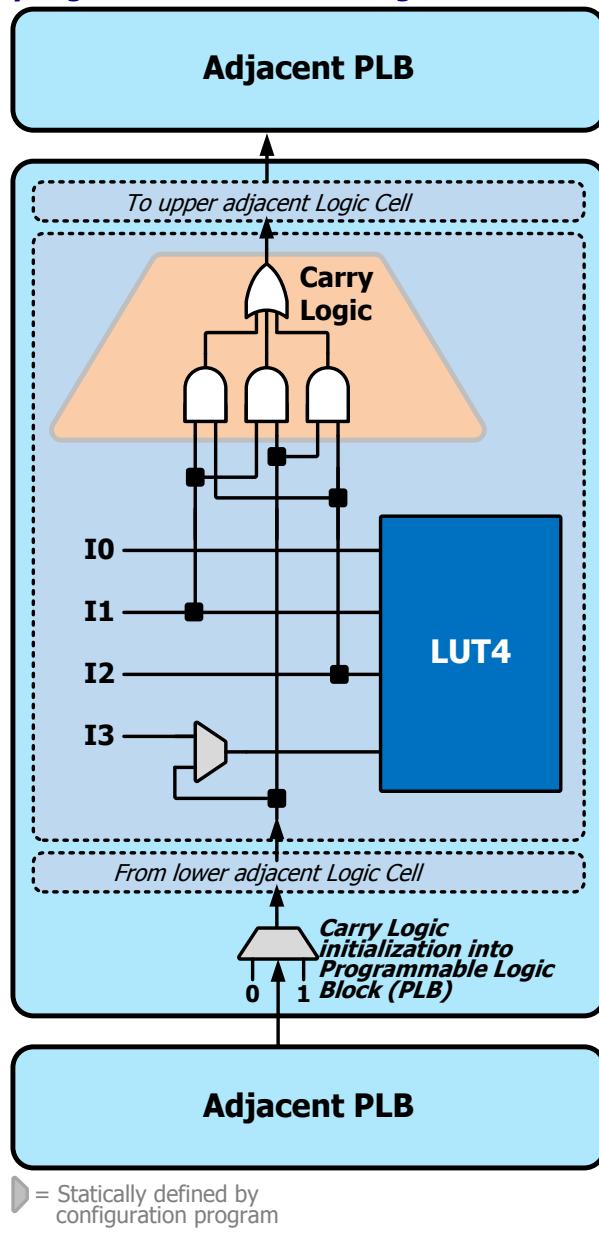

iCE65 Ultra Low-Power mobileFPGA™ Family

The Carry Logic generates the carry value to feed the next bit in the adder. The calculated carry value replaces the I3 input to the next LUT4 in the upper Logic Cell.

If required by the application, the carry output from the final stage of the adder is available by passing it through the final LUT4.

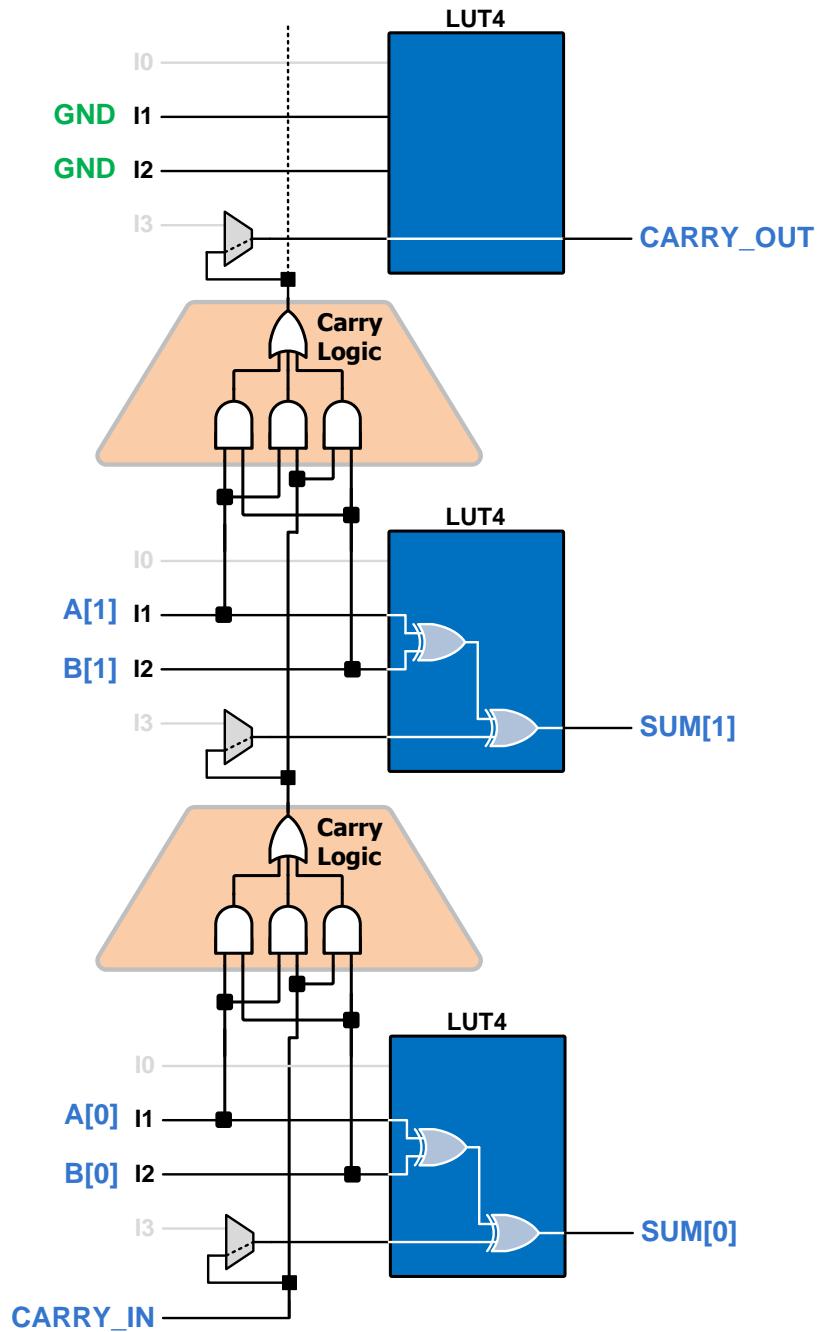

Figure 5: Carry Logic Structure within a Logic Cell and between PLBs

Implementing Subtractors, Decrementers

As mentioned earlier, the Carry Logic generates a High output whenever the sum of `I1 + I2 + CARRY_IN` generates a carry. The Carry Logic does not specifically have a subtract mode. To implement a subtract function or decrement function, logically invert either the `I1` or `I2` input and invert the initial carry input. This performs a 2s complement subtract operation.

Figure 6: Two-bit Adder Example

For best possible performance, the global buffer inputs (GBIN[7:0]) connect directly to the their associated global buffers (GBUF[7:0]), bypassing the PIO logic and iCEgate circuitry as shown in [Figure 7](#). Consequently, the direct GBIN-to-GBUF connection cannot be blocked by the iCEgate circuitry. However, it is possible to use iCEgate to block PIO-to-GBUF clock connections.

For additional information on using the iCEgate feature, please refer to the following application note.

[AN002: Using iCEgate Blocking for Ultra-Low Power](#)

Input Pull-Up Resistors on I/O Banks 0, 1, and 2

The PIO pins in I/O Banks 0, 1, and 2 have an optional input pull-up resistor. Pull-up resistors are not provided in iCE65L04 and iCE65L08 I/O Bank 3. During the iCE65 configuration process, the input pull-up resistor is unconditionally enabled and pulls the input to within a diode drop of the associated I/O bank supply voltage (VCCIO_#). This prevents any signals from floating on the circuit board during configuration.

After iCE65 configuration is complete, the input pull-up resistor is optional, defined by a configuration bit. The pull-up resistor is also useful to tie off unused PIO pins. The Lattice iCEcube development software defines all unused PIO pins in I/O Banks 0, 1 and 2 as inputs with the pull-up resistor turned on. The pull-up resistor value depends on the VCCIO voltage applied to the bank, as shown in [Table 49](#).

Note: JTAG inputs TCK, TDI and TMS do not have the input pull-up resistor and must be tied off to GND when unused, else VCCIO_1 draws current.

No Input Pull-up Resistors on I/O Bank 3 of iCE65L04 and iCE65L08

The PIO pins in I/O Bank 3 do not have an internal pull-up resistor. To minimize power consumption, tie unused PIO pins in Bank 3 to a known logic level or drive them as a disabled high-impedance output.

Input Hysteresis

Inputs typically have about 50 mV of hysteresis, as indicated in [Table 49](#).

Output and Output Enable Signal Path

As shown in [Figure 7](#), a signal from programmable interconnect feeds the OUT signal on a Programmable I/O pad. This output connects either directly to the associated package pin or is held in an optional output flip-flop. Because all flip-flops are automatically reset after configuration, the output from the output flip-flop can be optionally inverted so that an active-Low output signal is held in the disabled (High) state immediately after configuration.

Similarly, each Programmable I/O pin has an output enable or three-state control called OE. When OE = High, the OUT output signal drives the associated pad, as described in [Table 10](#). When OE = Low, the output driver is in the high-impedance (Hi-Z) state. The OE output enable control signal itself connects either directly to the output buffer or is held in an optional register. The output buffer is optionally permanently enabled or permanently disabled, either to unconditionally drive output signals, or to allow input-only signals.

Table 10: PIO Output Operations (non-registered operation, no inversions)

Operation	OUT	OE	PAD
	Data Output	Enable	
Three-State	X	0	Hi-Z
Drive Output Data	OUT	1*	OUT

X = don't care, 1* = High or unused, Hi-Z = high-impedance, three-stated, floating.

See [Input and Output Register Control per PIO Pair](#) for information about the registered input path.

Global Routing Resources

Global Buffers

Each iCE65 component has eight global buffer routing connections, illustrated in Figure 14. There are eight high-drive buffers, connected to the eight low-skew, global lines. These lines are designed primarily for clock distribution but are also useful for other high-fanout signals such as set/reset and enable signals. The global buffers originate either from the Global Buffer Inputs (GBINx) or from programmable interconnect. The associated GBINx pin represents the best pin to drive a global buffer from an external source. However, the application with an iCE65 FPGA can also drive a global buffer via any other PIO pin or from internal logic using the programmable interconnect.

If not used in an application, individual global buffers are turned off to save power.

Figure 14: High-drive, Low-skew, High-fanout Global Buffer Routing Resources

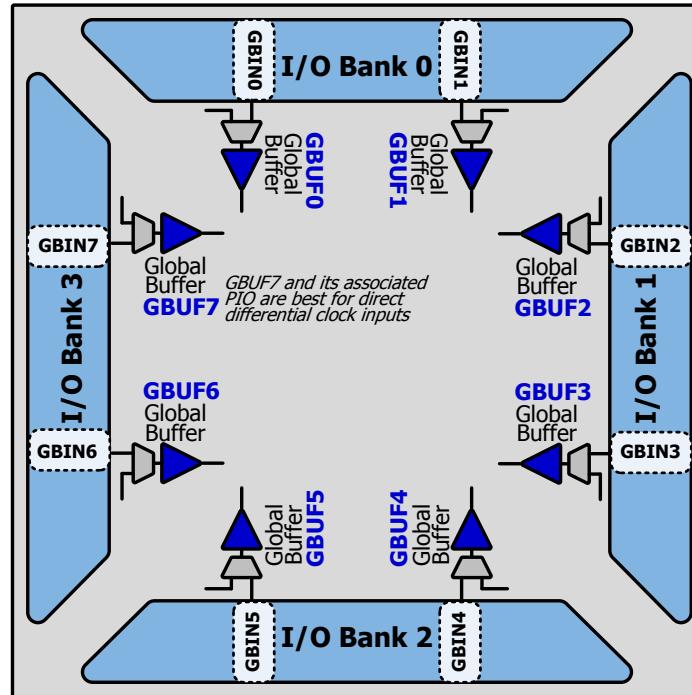

Table 11 lists the connections between a specific global buffer and the inputs on a Programmable Logic Block (PLB). All global buffers optionally connect to all clock inputs. Any four of the eight global buffers can drive logic inputs to a PLB. Even-numbered global buffers optionally drive the Reset input to a PLB. Similarly, odd-numbered buffers optionally drive the PLB clock-enable input.

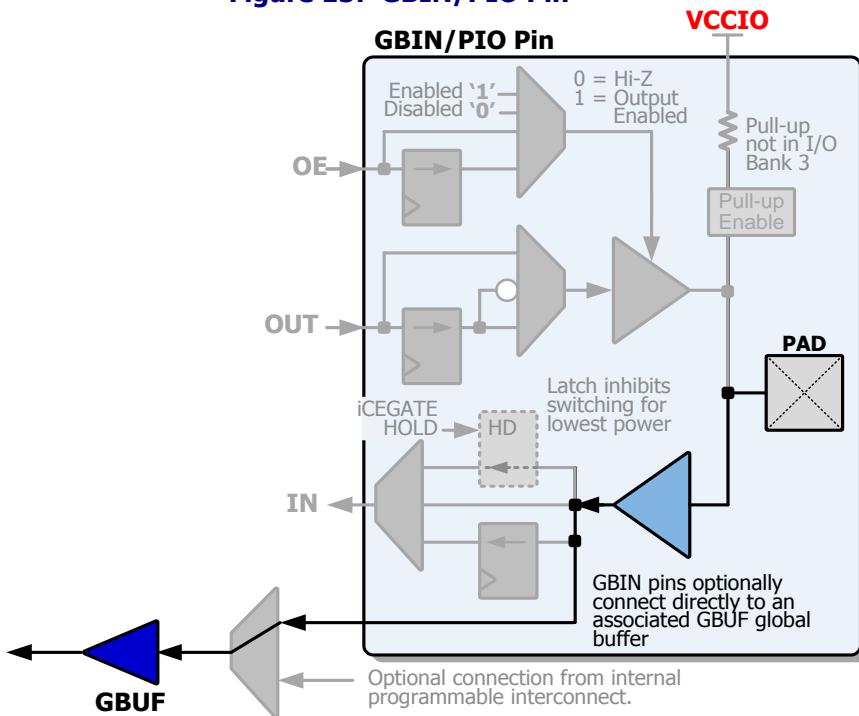

Table 11: Global Buffer (GBUF) Connections to Programmable Logic Block (PLB)

Global Buffer	LUT Inputs	Clock	Clock Enable	Reset
GBUF0	Yes, any 4 of 8 GBUF buffers	Yes	Yes	No
GBUF1		Yes	No	Yes
GBUF2		Yes	Yes	No
GBUF3		Yes	No	Yes
GBUF4		Yes	Yes	No
GBUF5		Yes	No	Yes
GBUF6		Yes	Yes	No
GBUF7		Yes	No	Yes

Note the clock differences between the iCE65L04 and iCE65L08 in the CB196 package.

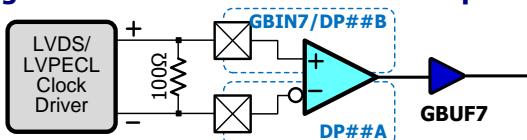

Figure 15: GBIN/PIO Pin

Differential Global Buffer Input

All eight global buffer inputs support single-ended I/O standards such as LVCMOS. Global buffer GBUF7 in I/O Bank 3 also provides an optional direct SubLVDS, LVDS, or LVPECL differential clock input, as shown in [Figure 16](#). The GBIN7 and its associated differential I/O pad accept a differential clock signal. A $100\ \Omega$ termination resistor is required across the two pads. Optionally, swap the outputs from the LVDS or LVPECL clock driver to invert the clock as it enters the iCE65 device.

Figure 16: LVDS or LVPECL Clock Input

[Table 15](#) lists the pin or ball numbers for the differential global buffer input by package style. Although this differential input is the only one that connects directly to a global buffer, other differential inputs can connect to a global buffer using general-purpose interconnect, with slightly more signal delay.

Table 15: Differential Global Buffer Input Ball/Pin Number by Package

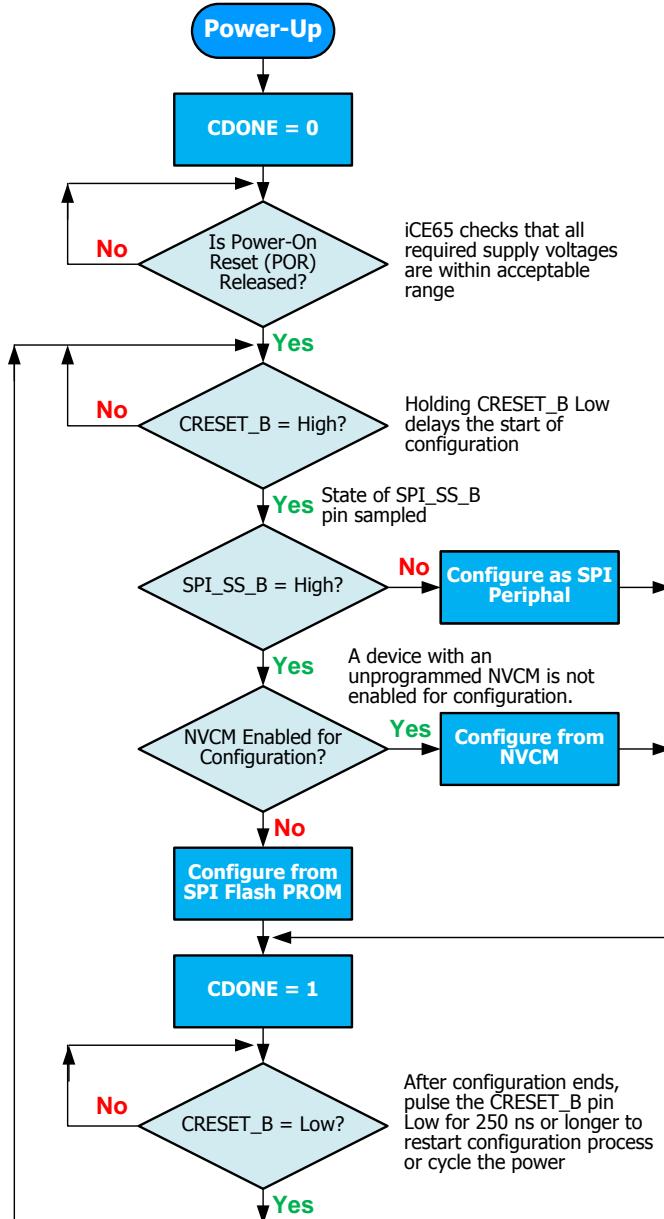

Differential Global Buffer Input (GBIN)	I/O Bank	VQ100	CB132	'L04 CB196	'L08 CB196	CB284
GBIN7/DPxxB	3	13	N/A	G1	H3	L5
DPxxA		12	N/A	G2	H4	L3

The differential global buffer input is not available for iCE65 devices in the CB132 package. This restriction is an artifact of the pin compatibility between the CB132 and CB284 package.

Note the clock differences between the iCE65L04 and iCE65L08 in the CB196 package.

Figure 20: Device Configuration Control Flow

Configuration Image Size

Table 23 shows the number of memory bits required to configure an iCE65 device. Two values are provided for each device. The “Logic Only” value indicates the minimum configuration size, the number of bits required to configure only the logic fabric, leaving the RAM4K blocks uninitialized. The “Logic + RAM4K” column indicates the maximum configuration size, the number of bits to configure the logic fabric and to pre-initialize all the RAM4K blocks.

Figure 24: SPI Release from Deep Power-down Command

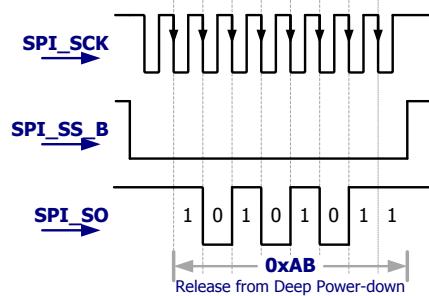

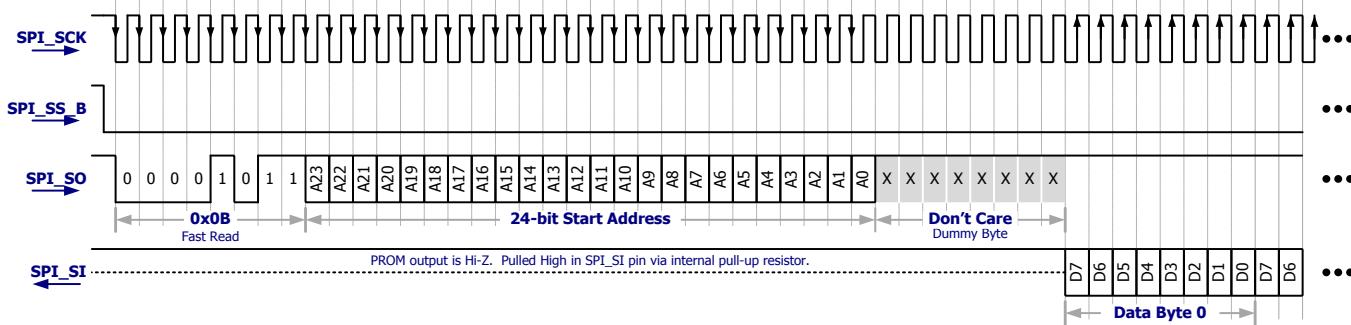

Figure 25 illustrates the next command issued by the iCE65 device. The iCE65 SPI interface again drives **SPI_SS_B** Low, followed by a Fast Read command, hexadecimal command code **0x0B**, followed by a 24-bit start address, transmitted on the **SPI_SO** output. The iCE65 device provides data on the falling edge of **SPI_SS_B**. Upon initial power-up, the start address is always **0x00_0000**. After waiting eight additional clock cycles, the iCE65 device begins reading serial data from the SPI PROM. Before presenting data, the SPI PROM's serial data output is high-impedance. The **SPI_SI** input pin has an internal pull-up resistor and sees high-impedance as logic '1'.

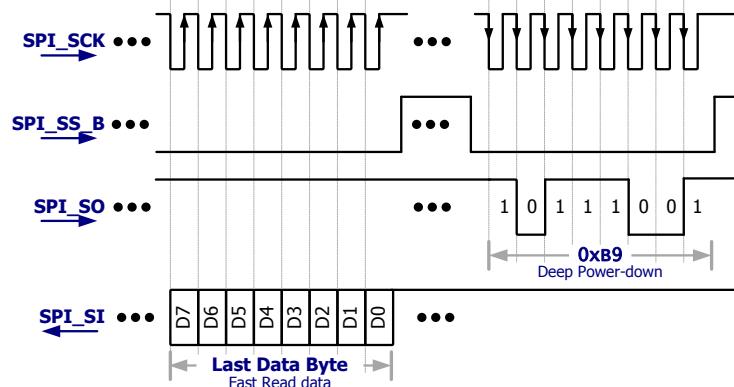

Figure 25: SPI Fast Read Command

The external SPI PROM supplies data on the falling edge of the iCE65 device's **SPI_SCK** clock output. The iCE65 device captures each PROM data value on the **SPI_SI** input, using the rising edge of the **SPI_SCK** clock signal. The SPI PROM data starts at the 24-bit address presented by the iCE65 device. PROM data is serially output, byte by byte, with most-significant bit, D7, presented first. The PROM automatically increments an internal byte counter as long as the PROM is selected and clocked.

After transferring the required number configuration data bits, the iCE65 device ends the Fast Read command by de-asserting its **SPI_SS_B** PROM select output, as shown in Figure 26. To conserve power, the iCE65 device then optionally issues a final Deep Power-down command, hexadecimal command code **0xB9**. After de-asserting the **SPI_SS_B** output, the SPI PROM enters its Deep Power-down mode. The final power-down step is optional; the application may use the SPI PROM and can skip this step, controlled by a configuration option.

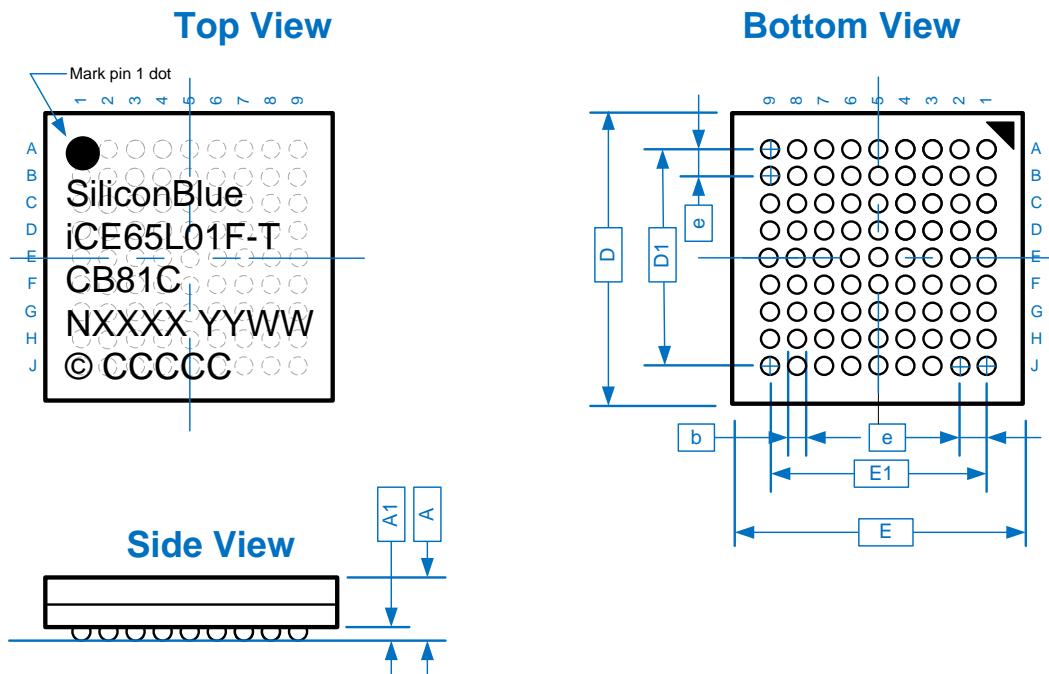

Figure 26: Final Configuration Data, SPI Deep Power-down Command

CB121 Chip-Scale Ball-Grid Array

The CB121 package is a chip-scale, fully-populated, ball-grid array with 0.5 mm ball pitch.

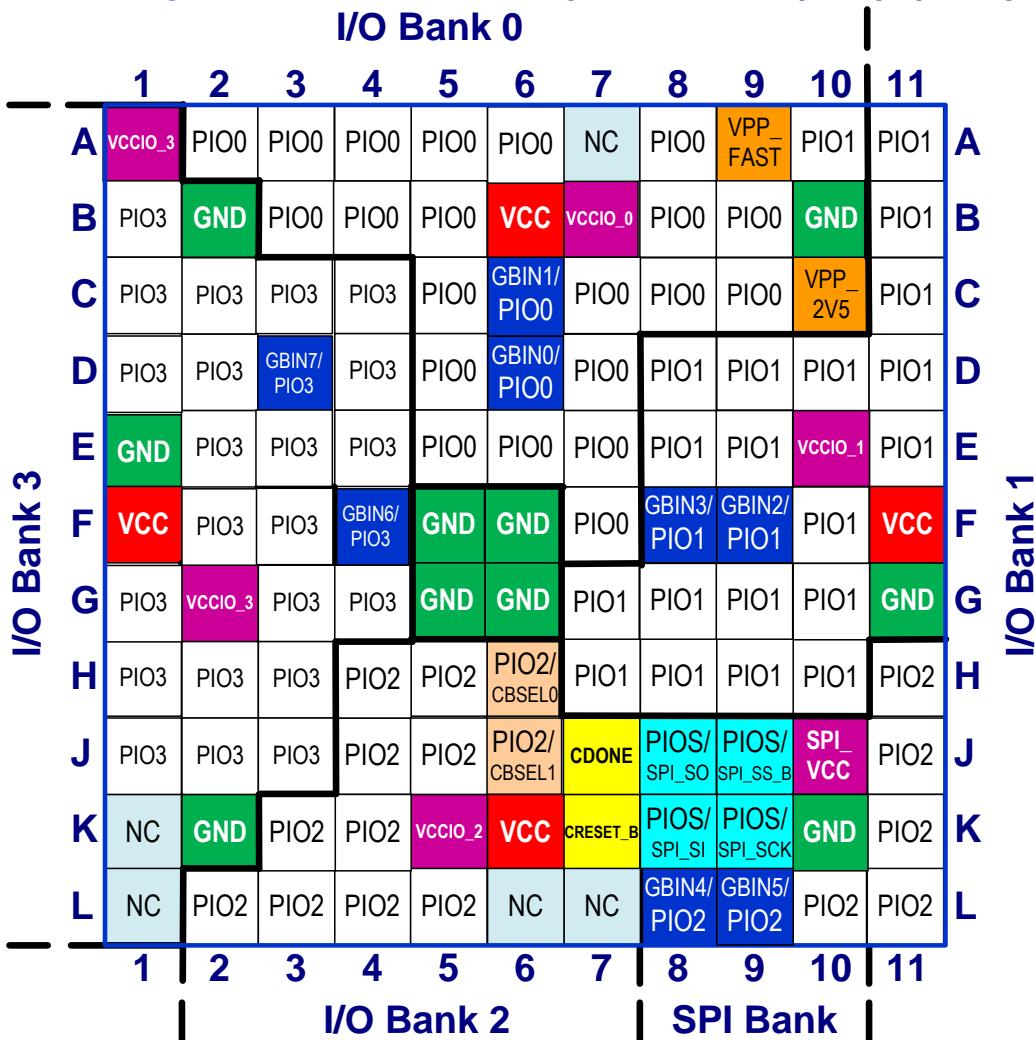

Footprint Diagram

Figure 39 shows the iCE65L01 chip-scale BGA footprint for the 6 x 6 mm CB121 package.

Also see Table 40 for a complete, detailed pinout for the 121-ball chip-scale BGA packages.

The signal pins are also grouped into the four I/O Banks and the SPI interface.

Figure 39: iCE65L01 CB121 Chip-Scale BGA Footprint (Top View)

Pinout Table

Table 40 provides a detailed pinout table for the iCE65L01 in the CB121 chip-scale BGA package. Pins are generally arranged by I/O bank, then by ball function.

Table 40: iCE65L01 CB121 Chip-scale BGA Pinout Table

CB196 Chip-Scale Ball-Grid Array

The CB196 package is a chip-scale, fully-populated, ball-grid array with 0.5 mm ball pitch.

Footprint Diagram

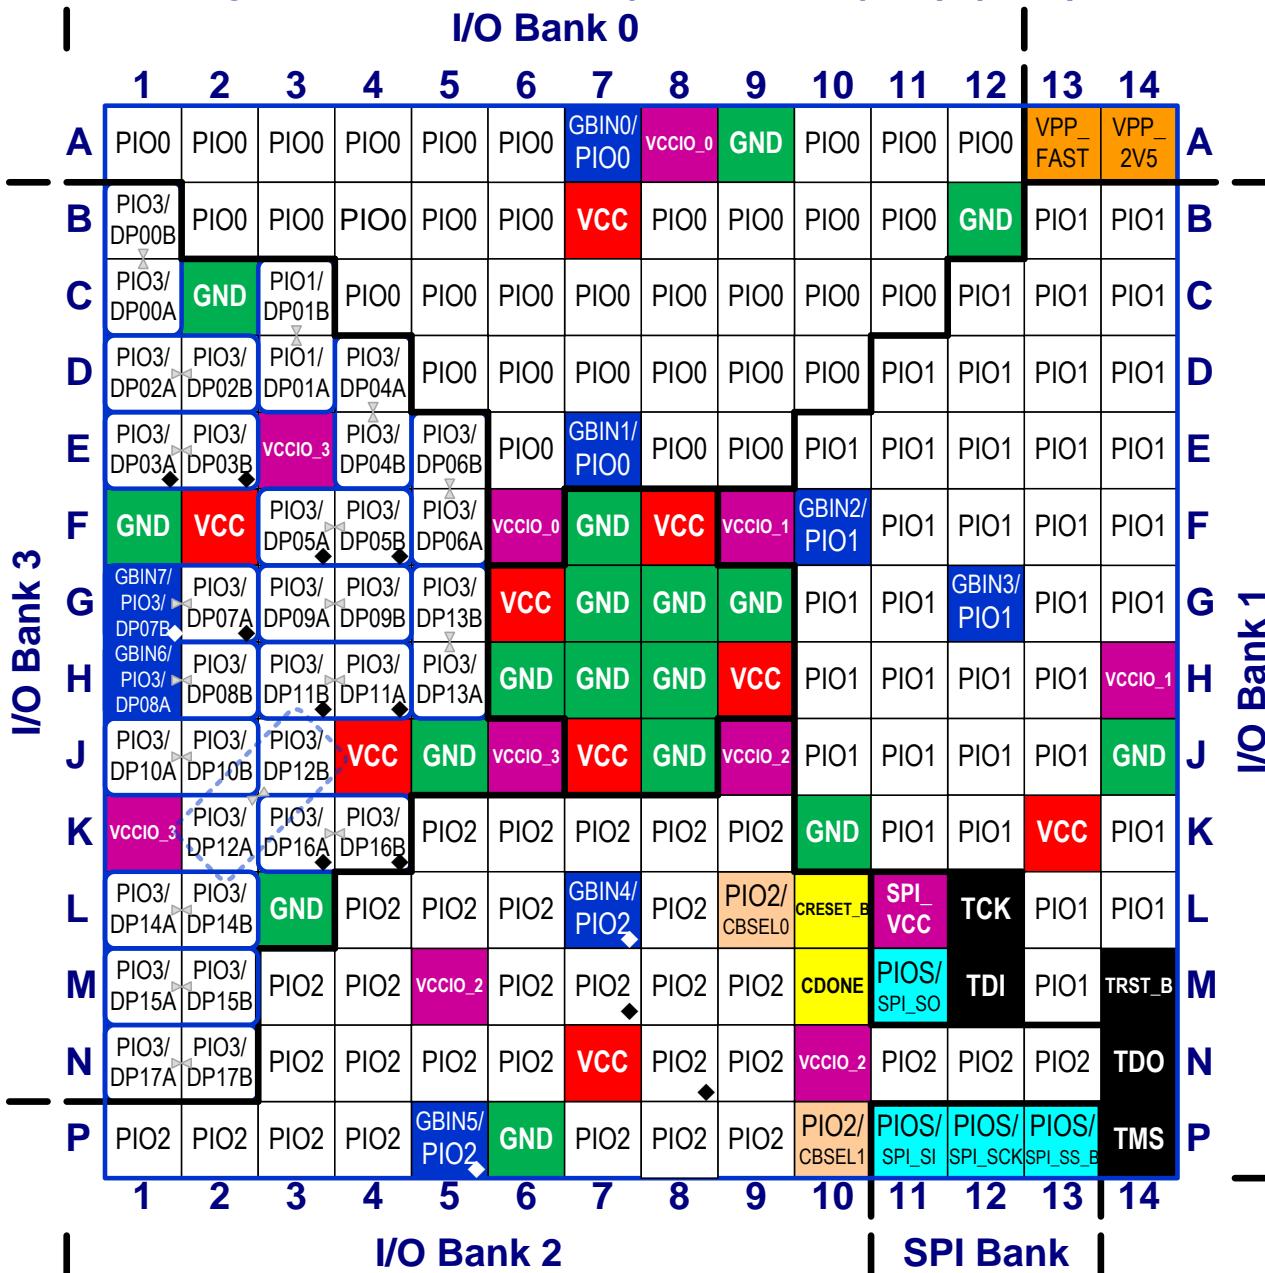

Figure 45 shows the iCE65L04 chip-scale BGA footprint for the 8 x 8 mm CB196 package. The footprint for the iCE65L08 is different than the iCE64L04 footprint, as shown in Figure 46. The pinout differences are highlighted by warning diamonds (◆) in the footprint diagrams and summarized in Table 43.

Although both the iCE65L04 and iCE65L08 are both available in the CB196 package and *almost* completely pin compatible, there are differences as shown in Table 43.

Figure 31 shows the conventions used in the diagram. Also see Table 42 for a complete, detailed pinout for the 196-ball chip-scale BGA packages. The signal pins are also grouped into the four I/O Banks and the SPI interface.

CB284 Chip-Scale Ball-Grid Array

The CB284 package, partially-populated 0.5 mm pitch, ball grid array simplifies PCB layout with empty ball rings.

Footprint Diagram

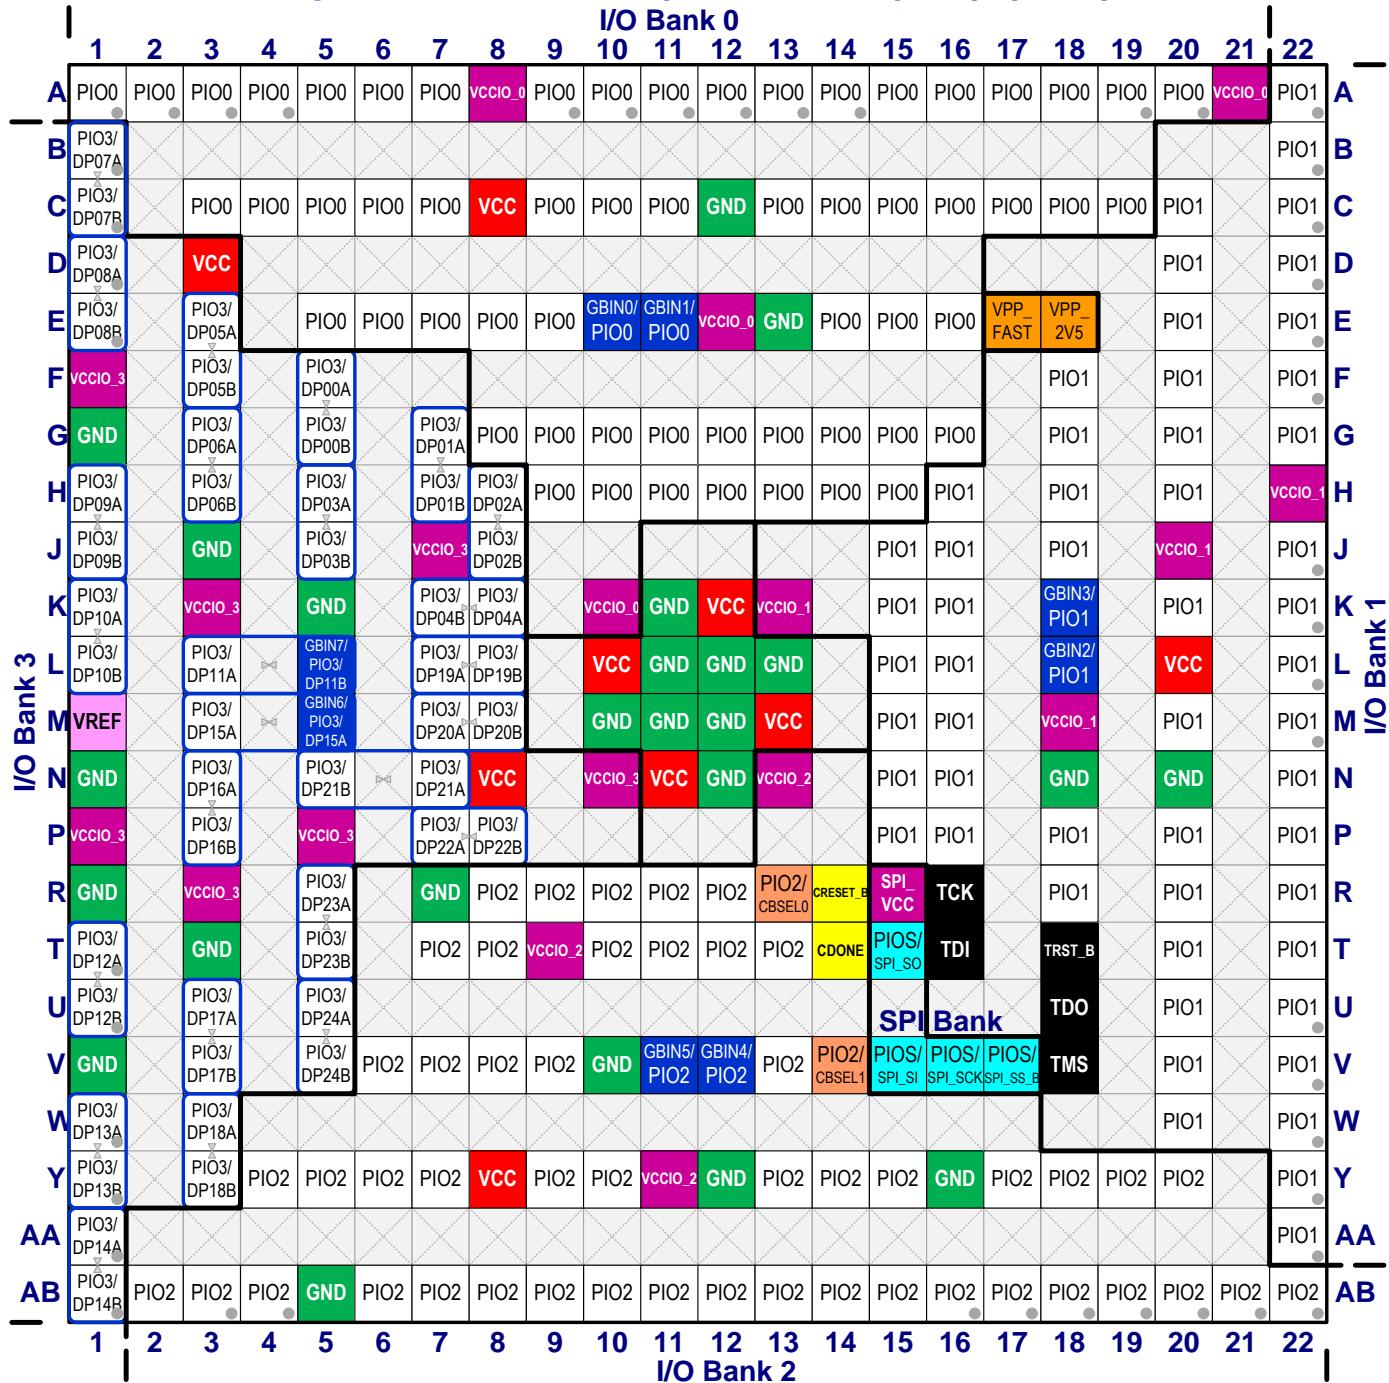

Figure 48 shows the CB284 chip-scale BGA footprint. The 8 x 8 mm CBI32 package fits within the same ball pattern as the 12 x 12 mm CB284 package. In other words, the central 8 x 8 section of the CB284 footprint matches the CBI32 footprint.

Figure 31 shows the conventions used in the diagram.

Also see Table 44 for a complete, detailed pinout for the 132-ball and 284-ball chip-scale BGA packages.

The signal pins are also grouped into the four I/O Banks and the SPI interface.

Figure 48: iCE65 CB284 Chip-Scale BGA Footprint (Top View)

Die Cross Reference

The tables in this section list all the pads on a specific die type and provide a cross reference on how a specific pad connects to a ball or pin in each of the available package offerings. Similarly, the tables provide the pad coordinates for the die-based version of the product (DiePlus). These tables also provide a way to prototype with one package option and then later move to a different package or die.

As described in “[Input and Output Register Control per PIO Pair](#)” on page 16, PIO pairs share register control inputs. Similarly, as described in “[Differential Inputs and Outputs](#)” on page 12, a PIO pair can form a differential input or output. PIO pairs in I/O Bank 3 are optionally differential inputs or differential outputs. PIO pairs in all other I/O Banks are optionally differential outputs. In the tables, differential pairs are surrounded by a heavy blue box.

iCE65L04

[Table 45](#) lists all the pads on the iCE65L04 die and how these pads connect to the balls or pins in the supported package styles. Most VCC, VCCIO, and GND pads are double-bonded inside the package although the table shows only a single connection.

For additional information on the iCE65L04 DiePlus product, please refer to the following data sheet.

Revision History

Version	Date	Description
2.42	30-MAR-2012	Changed company name. Updated Table 1
2.41	1-AUG-2011	Added VQ100 marking for NVCM programming.
2.4	13-MAY-2011	Added L01 CB121 package Figure 39 . Added note "else VCCIO_1 draws current" to JTAG inputs TCK, TDI and TMS do not have the input pull-up resistor and must be tied off to GND when unused, Table 32 . Input pin leakage current Table 49 split by bank. QN84 package drawing, Figure 35 , added note "underside metal is at ground potential", increased thermal resistance. Added Marking Format and Thermal resistance to CB81 Packag Mechanical Drawing Figure 33 . Added coplanarity specification to VQ100 Package Mechanical Drawing Figure 37
2.3	18-OCT-2010	Added L01 CB81 and L08 CB132 packages.
2.2.3	12-OCT-2010	Changed Figure 29: Application Processor Waveforms for SPI Peripheral Mode Configuration Process and Table 60 from 300 µs CRESET_B to 800 µs for iCE65L01/04 and 1200 µs for iCE65L08.
2.2.2	8-OCT-2010	Added iCE65L04 marking specification to Figure 47 CB196 Package Mechanical Drawing.
2.2.1	5-OCT-2010	Changed FSPI_SCK from 0.125 MHz to 1 MHz in SPI Peripheral Configuration Interface and in Table 60 .
2.2	6-AUG-2010	Programmable Interconnect section removed.
2.1.1	26-MAY-2010	Switched labels on Figure 53 LVCMOS Output High, VCCIO = 1.8V with VCCIO = 2.5V.
2.1	15-MAR-2010	Added JTAG unused input tie off guideline. Added marking specification and thermal characteristics to package drawings. Added production datasheet for iCE65L01 with timing update, including QN84, VQ100 and CB132. Added NVCM shut-off on SPI configuration. Added non-standard VCCIO operating conditions. Increased the minimum voltage supply specification for LVCMOS33 to 3.14V in Table 48 .
2.0.1	12-NOV-2009	Recommended Operation Conditions, Table 47 , replaced junction with ambient.
2.0	14-SEPT-2009	Finalized production data sheet for iCE65L04 and iCE65L08. Improved SubLVDS input specification V_{ICM} in Table 52 . CS63 and CC72 packages removed and placed in iCE DiCE KGD, Known Good Die datasheet. Added " IBIS Models for I/O Banks 0, 1, 2 and the SPI Bank ". Added " Printed Circuit Board Layout Information ".
1.5.1	13-JUL-2009	Updated the text in " SPI PROM Requirements " section. Minor label change in Figure 48 .
1.5	20-JUN-2009	Updated timing information and added -T high-speed device option (affected Figure 2 , Table 48 , Table 54 , Table 55 , Table 56 , and Table 61). Added support for 3.3V LVCMOS I/Os in I/O Bank 3 (affected Figure 7 , Table 5 , Table 7 , Table 8 , Table 47 , Table 48 , and Table 51). Added a section about the SPI Peripheral Configuration Interface and timing in Table 60 . Added a warning that a Warm Boot operation can only jump to another configuration image that has Warm Boot disabled. Updated configuration image size and configuration time for the iCE65L02 in Table 27 and Table 58 . Reduced the minimum voltage supply specification for LVCMOS33 to 2.7V in Table 48 . Added information about which power rails can be disconnected without effecting the Power-On Reset (POR) circuit and clarified description of VPP_2V5 pin in Table 36 . Added I/O characterization curves (Figure 52 , Figure 53 , and Figure 54). Minor changes to Figure 20 and Figure 21 . Changed timing per Figures 54-58 and Tables 55-57.
1.4.4	25-MAR-2009	Clarified the voltage requirements for the VPP_2V5 pin in Table 36 and notes under Table 48 .
1.4.3	9-MAR-2009	Removed volatile-only (-V) product offering from Figure 2 . Corrected NC on ball V22, removed it for ball T22 on CB284 package (Figure 48).
1.4.2	27-FEB-2009	Updated Table 14 , Table 23 , Table 26 , Table 30 , Table 33 , Table 35 , and Table 46 . Updated I/O Bank 3 information in Table 7 and Table 48 .
1.4.1	24-FEB-2009	Based on characterization data, reduced 32KHz operating current by 40% in Table 1 , Table 61 , and Figure 1 . Corrected that SSTL18 standards require VREF pin in Table 7 . Correct ball numbers for GBIN4/GBIN5 for CS110 package.
1.4	9-FEB-2009	Added footprint and pinout information for the VQ100 Very-thin Quad Flat Package. Added footprint for iCE65L08 in CB196 (Figure 46) and added Table 43 showing the differences between the 'L04 and 'L08 in the CB196 package. Unified the package footprint nomenclature in the Package and Pinout Information section. Added note to Global Buffer Inputs that the differential clock direct input is not available on the CB132 package. Added tables showing the ball/pin number for various control functions, by package (Table 14 , Table 23 , Table 26 , Table 30 , and Table 33). Corrected the GBIN/GBUF designations. GBIN4 and GBIN5 were swapped as were GBIN6 and GBIN7. This change affected all pinout tables and footprint diagrams. Updated and corrected " Differential Global Buffer Input ." Tested and corrected the clock-enable and reset connections between global buffers and various resources (Table 11 , Table 12 , and Table 13). Added " Automatic Global Buffer Insertion, Manual Insertion ." Added " Die Cross Reference " section. Improved industrial temperature range by lowering
