
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	eZ8
Core Size	8-Bit
Speed	20MHz
Connectivity	IrDA, UART/USART
Peripherals	Brown-out Detect/Reset, LED, LVD, POR, PWM, Temp Sensor, WDT
Number of I/O	23
Program Memory Size	8KB (8K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	1K x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	A/D 8x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 105°C (TA)
Mounting Type	Through Hole
Package / Case	28-DIP (0.600", 15.24mm)
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8f082apj020eg

Overview

Zilog's Z8 Encore! MCU family of products is the first in a line of Zilog microcontroller products based upon the 8-bit eZ8 CPU. Zilog's Z8 Encore! XP F082A Series products expand upon Zilog's extensive line of 8-bit microcontrollers. The Flash in-circuit programming capability allows for faster development time and program changes in the field. The new eZ8 CPU is upward compatible with existing Z8 instructions. The rich peripheral set of the Z8 Encore! XP F082A Series makes it suitable for a variety of applications including motor control, security systems, home appliances, personal electronic devices and sensors.

Features

The key features of Z8 Encore! XP F082A Series products include:

- 20 MHz eZ8 CPU
- 1 KB, 2 KB, 4 KB, or 8 KB Flash memory with in-circuit programming capability
- 256 B, 512 B, or 1 KB register RAM
- Up to 128 B nonvolatile data storage (NVDS)
- Internal precision oscillator trimmed to ±1% accuracy
- External crystal oscillator operating up to 20 MHz
- Optional 8-channel, 10-bit analog-to-digital converter (ADC)
- Optional on-chip temperature sensor
- On-chip analog comparator
- Optional on-chip low-power operational amplifier (LPO)
- Full-duplex UART
- The UART baud rate generator (BRG) can be configured and used as a basic 16-bit timer
- Infrared Data Association (IrDA)-compliant infrared encoder/decoders, integrated with the UART
- Two enhanced 16-bit timers with capture, compare and PWM capability
- Watchdog Timer (WDT) with dedicated internal RC oscillator
- Up to 20 vectored interrupts
- 6 to 25 I/O pins depending upon package
- Up to thirteen 5 V-tolerant input pins

Address Space

The eZ8 CPU can access the following three distinct address spaces:

- The Register File contains addresses for the general-purpose registers and the eZ8 CPU, peripheral and general-purpose I/O port control registers.
- The Program Memory contains addresses for all memory locations having executable code and/or data.
- The Data Memory contains addresses for all memory locations that contain data only.

These three address spaces are covered fully in the following subsections. For more information about eZ8 CPU and its address space, refer to the eZ8 CPU Core User Manual (UM0128), which is available for download on www.zilog.com.

Register File

The Register File address space in the Z8 Encore! MCU is 4 KB (4096 bytes). The Register File is composed of two sections: control registers and general-purpose registers. When instructions are executed, registers defined as sources are read and registers defined as destinations are written. The architecture of the eZ8 CPU allows all general-purpose registers to function as accumulators, address pointers, index registers, stack areas, or scratch pad memory.

The upper 256 bytes of the 4 KB Register File address space are reserved for control of the eZ8 CPU, the on-chip peripherals and the I/O ports. These registers are located at addresses from F00H to FFFH. Some of the addresses within the 256 B control register section are reserved (unavailable). Reading from a reserved Register File address returns an undefined value. Writing to reserved Register File addresses is not recommended and can produce unpredictable results.

The on-chip RAM always begins at address 000H in the Register File address space. The Z8 Encore! XP™ F082A Series devices contain 256 B to 1 KB of on-chip RAM. Reading from Register File addresses outside the available RAM addresses (and not within the control register address space) returns an undefined value. Writing to these Register File addresses produces no effect.

Program Memory

The eZ8 CPU supports 64 KB of Program Memory address space. The Z8 Encore! XP F082A Series devices contain 1 KB to 8 KB of on-chip Flash memory in the Program Memory address space, depending on the device. Reading from Program Memory

Low-Power Modes

The Z8 Encore! XP F082A Series products contain power-saving features. The highest level of power reduction is provided by the STOP Mode, in which nearly all device functions are powered down. The next lower level of power reduction is provided by the HALT Mode, in which the CPU is powered down.

Further power savings can be implemented by disabling individual peripheral blocks while in Active mode (defined as being in neither STOP nor HALT Mode).

STOP Mode

Executing the eZ8 CPU's STOP instruction places the device into STOP Mode, powering down all peripherals except the Voltage Brown-Out detector, the Low-power Operational Amplifier and the Watchdog Timer. These three blocks may also be disabled for additional power savings. Specifically, the operating characteristics are:

- Primary crystal oscillator and internal precision oscillator are stopped; X_{IN} and X_{OUT} (if previously enabled) are disabled and PA0/PA1 revert to the states programmed by the GPIO registers
- System clock is stopped
- eZ8 CPU is stopped
- Program counter (PC) stops incrementing
- Watchdog Timer's internal RC oscillator continues to operate if enabled by the Oscillator Control Register
- If enabled, the Watchdog Timer logic continues to operate
- If enabled for operation in STOP Mode by the associated Flash option bit, the Voltage Brown-Out protection circuit continues to operate
- Low-power operational amplifier continues to operate if enabled by the Power Control Register
- All other on-chip peripherals are idle

To minimize current in STOP Mode, all GPIO pins that are configured as digital inputs must be driven to one of the supply rails (V_{CC} or GND). Additionally, any GPIOs configured as outputs must also be driven to one of the supply rails. The device can be brought out of STOP Mode using Stop Mode Recovery. For more information about Stop Mode Recovery, see the Reset, Stop Mode Recovery and Low Voltage Detection chapter on page 22.

Table 15. Port Alternate Function Mapping (Non 8-Pin Parts)

Port	Pin	Mnemonic	Alternate Function Description	Alternate Function Set Register AFS1
Port A [1,2]	PA0	T0IN/$\overline{\text{T0OUT}}$	Timer 0 Input/Timer 0 Output Complement	N/A
		Reserved		
	PA1	T0OUT	Timer 0 Output	
		Reserved		
	PA2	DE0	UART 0 Driver Enable	
		Reserved		
	PA3	$\overline{\text{CTS0}}$	$\overline{\text{UART 0 Clear to Send}}$	
		Reserved		
	PA4	RXD0/IRRX0	UART 0/IrDA 0 Receive Data	
		Reserved		
	PA5	TXD0/IRTX0	UART 0/IrDA 0 Transmit Data	
		Reserved		
	PA6	T1IN/$\overline{\text{T1OUT}}$	Timer 1 Input/Timer 1 Output Complement	
		Reserved		
	PA7	T1OUT	Timer 1 Output	
		Reserved		

Notes:
1. Because there is only a single alternate function for each Port A pin, the Alternate Function Set registers are not implemented for Port A. Enabling alternate function selections automatically enables the associated alternate function. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
2. Whether PA0/PA6 takes on the timer input or timer output complement function depends on the timer configuration. See the Timer Pin Signal Operation section on page 84 for details.
3. Because there are at most two choices of alternate function for any pin of Port B, the Alternate Function Set Register AFS2 is not used to select the function. Alternate function selection must also be enabled. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
4. V_{REF} is available on PB5 in 28-pin products and on PC2 in 20-pin parts.
5. Because there are at most two choices of alternate function for any pin of Port C, the Alternate Function Set Register AFS2 is not used to select the function. Alternate function selection must also be enabled. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
6. Because there is only a single alternate function for the Port PD0 pin, the Alternate Function Set registers are not implemented for Port D. Enabling alternate function selections automatically enables the associated alternate function. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.

Table 15. Port Alternate Function Mapping (Non 8-Pin Parts) (Continued)

Port	Pin	Mnemonic	Alternate Function Description	Alternate Function Set Register AFS1
Port B [3]	PB0	Reserved		AFS1[0]: 0
		ANA0/AMPOUT	ADC Analog Input/LPO Output	AFS1[0]: 1
	PB1	Reserved		AFS1[1]: 0
		ANA1/AMPINN	ADC Analog Input/LPO Input (N)	AFS1[1]: 1
	PB2	Reserved		AFS1[2]: 0
		ANA2/AMPINP	ADC Analog Input/LPO Input (P)	AFS1[2]: 1
	PB3	CLKIN	External Clock Input	AFS1[3]: 0
		ANA3	ADC Analog Input	AFS1[3]: 1
	PB4	Reserved		AFS1[4]: 0
		ANA7	ADC Analog Input	AFS1[4]: 1
	PB5	Reserved		AFS1[5]: 0
		V_{REF} [4]	ADC Voltage Reference	AFS1[5]: 1
	PB6	Reserved		AFS1[6]: 0
		Reserved		AFS1[6]: 1
	PB7	Reserved		AFS1[7]: 0
		Reserved		AFS1[7]: 1

Notes:
1. Because there is only a single alternate function for each Port A pin, the Alternate Function Set registers are not implemented for Port A. Enabling alternate function selections automatically enables the associated alternate function. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
2. Whether PA0/PA6 takes on the timer input or timer output complement function depends on the timer configuration. See the Timer Pin Signal Operation section on page 84 for details.
3. Because there are at most two choices of alternate function for any pin of Port B, the Alternate Function Set Register AFS2 is not used to select the function. Alternate function selection must also be enabled. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
4. V_{REF} is available on PB5 in 28-pin products and on PC2 in 20-pin parts.
5. Because there are at most two choices of alternate function for any pin of Port C, the Alternate Function Set Register AFS2 is not used to select the function. Alternate function selection must also be enabled. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
6. Because there is only a single alternate function for the Port PD0 pin, the Alternate Function Set registers are not implemented for Port D. Enabling alternate function selections automatically enables the associated alternate function. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.

Table 15. Port Alternate Function Mapping (Non 8-Pin Parts) (Continued)

Port	Pin	Mnemonic	Alternate Function Description	Alternate Function Set Register AFS1
Port C [5]	PC0	Reserved		AFS1[0]: 0
		ANA4/CINP	ADC or Comparator Input	AFS1[0]: 1
	PC1	Reserved		AFS1[1]: 0

				AFS1[5]: 1
	PC6	Reserved		AFS1[6]: 0
				AFS1[6]: 1
	PC7	Reserved		AFS1[7]: 0
				AFS1[7]: 1
Port D [6]	PD0	$\overline{\text{RESET}}$	External Reset	N/A

Notes:
1. Because there is only a single alternate function for each Port A pin, the Alternate Function Set registers are not implemented for Port A. Enabling alternate function selections automatically enables the associated alternate function. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
2. Whether PA0/PA6 takes on the timer input or timer output complement function depends on the timer configuration. See the Timer Pin Signal Operation section on page 84 for details.
3. Because there are at most two choices of alternate function for any pin of Port B, the Alternate Function Set Register AFS2 is not used to select the function. Alternate function selection must also be enabled. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
4. V_{REF} is available on PB5 in 28-pin products and on PC2 in 20-pin parts.
5. Because there are at most two choices of alternate function for any pin of Port C, the Alternate Function Set Register AFS2 is not used to select the function. Alternate function selection must also be enabled. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.
6. Because there is only a single alternate function for the Port PD0 pin, the Alternate Function Set registers are not implemented for Port D. Enabling alternate function selections automatically enables the associated alternate function. See the Port A–D Alternate Function Subregisters (PxAF) section on page 47 for details.

Port A–D Stop Mode Recovery Source Enable Subregisters

The Port A–D Stop Mode Recovery Source Enable Subregister, shown in Table 25, is accessed through the Port A–D Control Register by writing 05H to the Port A–D Address Register. Setting the bits in the Port A–D Stop Mode Recovery Source Enable subregisters to 1 configures the specified port pins as a Stop Mode Recovery source. During STOP Mode, any logic transition on a port pin enabled as a Stop Mode Recovery source initiates Stop Mode Recovery.

Table 25. Port A–D Stop Mode Recovery Source Enable Subregisters (PxSMRE)

Bit	7	6	5	4	3	2	1	0
Field	PSMRE7	PSMRE6	PSMRE5	PSMRE4	PSMRE3	PSMRE2	PSMRE1	PSMRE0
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	If 05H in Port A–D Address Register, accessible through the Port A–D Control Register							

Bit	Description
[7:0] PSMREx	Port Stop Mode Recovery Source Enabled 0 = The port pin is not configured as a Stop Mode Recovery source. Transitions on this pin during STOP Mode do not initiate Stop Mode Recovery. 1 = The port pin is configured as a Stop Mode Recovery source. Any logic transition on this pin during STOP Mode initiates Stop Mode Recovery.

Note: x indicates the specific GPIO port pin number (7–0).

Port A–C Input Data Registers

Reading from the Port A–C Input Data registers, shown in Table 29, return the sampled values from the corresponding port pins. The Port A–C Input Data registers are read-only. The value returned for any unused ports is 0. Unused ports include those missing on the 8- and 28-pin packages, as well as those missing on the ADC-enabled 28-pin packages.

Table 29. Port A–C Input Data Registers (PxIN)

Bit	7	6	5	4	3	2	1	0
Field	PIN7	PIN6	PIN5	PIN4	PIN3	PIN2	PIN1	PIN0
RESET	X	X	X	X	X	X	X	X
R/W	R	R	R	R	R	R	R	R
Address	FD2H, FD6H, FDAH							

X = Undefined.

Bit	Description
[7:0] PxIN	Port Input Data Sampled data from the corresponding port pin input. 0 = Input data is logical 0 (Low). 1 = Input data is logical 1 (High).

Note: x indicates the specific GPIO port pin number (7–0).

Port A–D Output Data Register

The Port A–D Output Data Register, shown in Table 30, controls the output data to the pins.

Table 30. Port A–D Output Data Register (PxOUT)

Bit	7	6	5	4	3	2	1	0
Field	POUT7	POUT6	POUT5	POUT4	POUT3	POUT2	POUT1	POUT0
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	FD3H, FD7H, FDBH, FDFH							

Bit	Description
[7:0] PxOUT	Port Output Data These bits contain the data to be driven to the port pins. The values are only driven if the corresponding pin is configured as an output and the pin is not configured for alternate function operation. 0 = Drive a logical 0 (Low). 1 = Drive a logical 1 (High). High value is not driven if the drain has been disabled by setting the corresponding Port Output Control Register bit to 1.

Note: x indicates the specific GPIO port pin number (7–0).

- Writing a 1 to the IRQE bit in the Interrupt Control Register

Interrupts are globally disabled by any of the following actions:

- Execution of a Disable Interrupt (DI) instruction
- eZ8 CPU acknowledgement of an interrupt service request from the interrupt controller
- Writing a 0 to the IRQE bit in the Interrupt Control Register
- Reset
- Execution of a Trap instruction
- Illegal Instruction Trap
- Primary Oscillator Fail Trap
- Watchdog Oscillator Fail Trap

Interrupt Vectors and Priority

The interrupt controller supports three levels of interrupt priority. Level 3 is the highest priority, Level 2 is the second highest priority and Level 1 is the lowest priority. If all of the interrupts are enabled with identical interrupt priority (all as Level 2 interrupts, for example), the interrupt priority is assigned from highest to lowest as specified in Table 34 on page 56. Level 3 interrupts are always assigned higher priority than Level 2 interrupts which, in turn, always are assigned higher priority than Level 1 interrupts. Within each interrupt priority level (Level 1, Level 2, or Level 3), priority is assigned as specified in Table 34, above. Reset, Watchdog Timer interrupt (if enabled), Primary Oscillator Fail Trap, Watchdog Oscillator Fail Trap and Illegal Instruction Trap always have highest (level 3) priority.

Interrupt Assertion

Interrupt sources assert their interrupt requests for only a single system clock period (single pulse). When the interrupt request is acknowledged by the eZ8 CPU, the corresponding bit in the Interrupt Request Register is cleared until the next interrupt occurs. Writing a 0 to the corresponding bit in the Interrupt Request Register likewise clears the interrupt request.

! Caution: Zilog recommends not using a coding style that clears bits in the Interrupt Request registers. All incoming interrupts received between execution of the first LDX command and the final LDX command are lost. See Example 1, which follows.

The timer input can be used as a selectable counting source. It shares the same pin as the complementary timer output. When selected by the GPIO Alternate Function registers, this pin functions as a timer input in all modes except for the DUAL PWM OUTPUT mode. For this mode, there is no timer input available.

Timer Control Register Definitions

This section defines the features of the following Timer Control registers.

Timer 0–1 Control Registers see page 85

Timer 0–1 High and Low Byte Registers see page 89

Timer Reload High and Low Byte Registers see page 91

Timer 0–1 PWM High and Low Byte Registers see page 92

Timer 0–1 Control Registers

The Timer Control registers are 8-bit read/write registers that control the operation of their associated counter/timers.

Time 0–1 Control Register 0

The Timer Control Register 0 (TxCTL0) and Timer Control Register 1 (TxCTL1), shown in Table 50, determine the timer operating mode. These registers each include a programmable PWM deadband delay, two bits to configure timer interrupt definition and a status bit to identify if the most recent timer interrupt is caused by an input capture event.

Table 50. Timer 0–1 Control Register 0 (TxCTL0)

Bit	7	6	5	4	3	2	1	0
Field	TMODEHI	TICONFIG		Reserved	PWMD			INPCAP
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R
Address	F06H, F0EH							

Bit	Description
[7] TMODEHI	Timer Mode High Bit This bit, along with the TMODE field in the TxCTL1 Register, determines the operating mode of the timer. This bit is the most significant bit of the Timer mode selection value. See the description of the Timer 0–1 Control Register 1 (TxCTL1) for details about the full timer mode decoding.

Bit	Description (Continued)
[5:3] PRES	Prescale value The timer input clock is divided by 2^{PRES}, where PRES can be set from 0 to 7. The prescaler is reset each time the Timer is disabled. This reset ensures proper clock division each time the Timer is restarted. 000 = Divide by 1. 001 = Divide by 2. 010 = Divide by 4. 011 = Divide by 8. 100 = Divide by 16. 101 = Divide by 32. 110 = Divide by 64. 111 = Divide by 128.
[2:0] TMODE	Timer Mode This field, along with the TMODEHI bit in the TxCTL0 Register, determines the operating mode of the timer. TMODEHI is the most significant bit of the Timer mode selection value. The entire operating mode bits are expressed as {TMODEHI, TMODE[2:0]}. The TMODEHI is bit 7 of the TxCTL0 Register while TMODE[2:0] is the lower 3 bits of the TxCTL1 Register. 0000 = ONE-SHOT Mode. 0001 = CONTINUOUS Mode. 0010 = COUNTER Mode. 0011 = PWM SINGLE OUTPUT Mode. 0100 = CAPTURE Mode. 0101 = COMPARE Mode. 0110 = GATED Mode. 0111 = CAPTURE/COMPARE Mode. 1000 = PWM DUAL OUTPUT Mode. 1001 = CAPTURE RESTART Mode. 1010 = COMPARATOR COUNTER Mode.

Timer 0–1 High and Low Byte Registers

The Timer 0–1 High and Low Byte (TxH and TxL) registers, shown in Tables 52 and 53, contain the current 16-bit timer count value. When the timer is enabled, a read from TxH causes the value in TxL to be stored in a temporary holding register. A read from TxL always returns this temporary register when the timers are enabled. When the timer is disabled, reads from TxL read the register directly.

Writing to the Timer High and Low Byte registers while the timer is enabled is not recommended. There are no temporary holding registers available for write operations, so simultaneous 16-bit writes are not possible. If either the Timer High or Low Byte registers are written during counting, the 8-bit written value is placed in the counter (High or Low Byte) at the next clock edge. The counter continues counting from the new value.

The third scheme is enabled by setting MPMD[1:0] to 11b and by writing the UART's address into the UART Address Compare Register. This mode is identical to the second scheme, except that there are no interrupts on address bytes. The first data byte of each frame remains accompanied by a NEWFRM assertion.

External Driver Enable

The UART provides a Driver Enable (DE) signal for off-chip bus transceivers. This feature reduces the software overhead associated with using a GPIO pin to control the transceiver when communicating on a multi-transceiver bus, such as RS-485.

Driver Enable is an active High signal that envelopes the entire transmitted data frame including parity and Stop bits as displayed in Figure 14. The Driver Enable signal asserts when a byte is written to the UART Transmit Data Register. The Driver Enable signal asserts at least one UART bit period and no greater than two UART bit periods before the Start bit is transmitted. This allows a setup time to enable the transceiver. The Driver Enable signal deasserts one system clock period after the final Stop bit is transmitted. This one system clock delay allows both time for data to clear the transceiver before disabling it, plus the ability to determine if another character follows the current character. In the event of back to back characters (new data must be written to the Transmit Data Register before the previous character is completely transmitted) the DE signal is not deasserted between characters. The DEPOL bit in the UART Control Register 1 sets the polarity of the Driver Enable signal.

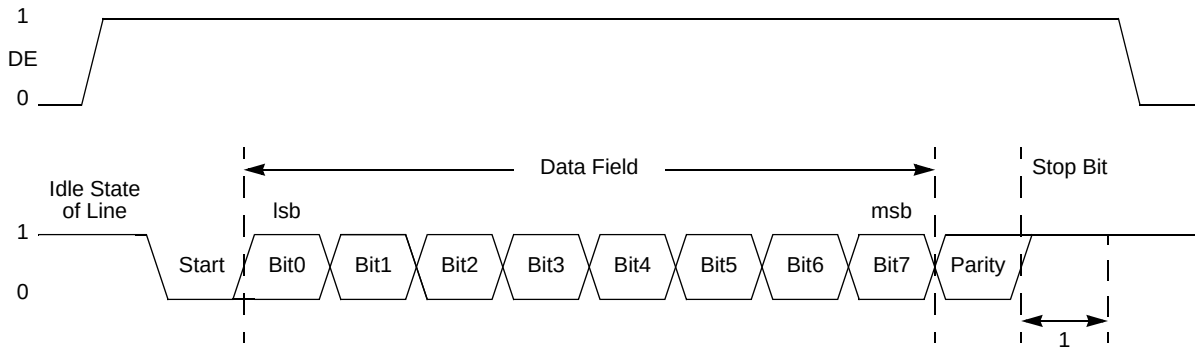

Figure 14. UART Driver Enable Signal Timing (shown with 1 Stop Bit and Parity)

The Driver Enable-to-Start bit setup time is calculated as follows:

$$\text{DE to Start Bit Setup Time (s)} \geq \frac{1}{\text{Baud Rate (Hz)}} \quad \text{and} \quad \leq \frac{2}{\text{Baud Rate (Hz)}}$$

Bit	Description (Continued)
[2] BRGCTL	Baud Rate Control This bit causes an alternate UART behavior depending on the value of the REN bit in the UART Control 0 Register. When the UART receiver is not enabled (REN=0), this bit determines whether the Baud Rate Generator issues interrupts. 0 = Reads from the Baud Rate High and Low Byte registers return the BRG reload value. 1 = The Baud Rate Generator generates a receive interrupt when it counts down to 0. Reads from the Baud Rate High and Low Byte registers return the current BRG count value. When the UART receiver is enabled (REN=1), this bit allows reads from the Baud Rate registers to return the BRG count value instead of the reload value. 0 = Reads from the Baud Rate High and Low Byte registers return the BRG reload value. 1 = Reads from the Baud Rate High and Low Byte registers return the current BRG count value. Unlike the Timers, there is no mechanism to latch the Low Byte when the High Byte is read.
[1] RDAIRQ	Receive Data Interrupt Enable 0 = Received data and receiver errors generates an interrupt request to the Interrupt Controller. 1 = Received data does not generate an interrupt request to the Interrupt Controller. Only receiver errors generate an interrupt request.
[0] IREN	Infrared Encoder/Decoder Enable 0 = Infrared Encoder/Decoder is disabled. UART operates normally. 1 = Infrared Encoder/Decoder is enabled. The UART transmits and receives data through the Infrared Encoder/Decoder.

Table 75. ADC Data High Byte Register (ADCD_H)

Bit	7	6	5	4	3	2	1	0
Field	ADCDH							
RESET	X	X	X	X	X	X	X	X
R/W	R	R	R	R	R	R	R	R
Address	F72H							
X = Undefined.								

Bit	Description
[7:0] ADCDH	ADC Data High Byte This byte contains the upper eight bits of the ADC output. These bits are not valid during a single-shot conversion. During a continuous conversion, the most recent conversion output is held in this register. These bits are undefined after a Reset.

ADC Data Low Byte Register

The ADC Data Low Byte (ADCD_L) Register contains the lower bits of the ADC output plus an overflow status bit. The output is a 13-bit two's complement value. During a single-shot conversion, this value is invalid. Access to the ADC Data Low Byte Register is read-only. Reading the ADC Data High Byte Register latches data in the ADC Low Bits Register.

Table 76. ADC Data Low Byte Register (ADCD_L)

Bit	7	6	5	4	3	2	1	0
Field	ADCDL					Reserved		OVF
RESET	X	X	X	X	X	X	X	X
R/W	R	R	R	R	R	R	R	R
Address	F73H							
X = Undefined.								

Bit	Description
[7:3] ADCDL	ADC Data Low Bits These bits are the least significant five bits of the 13-bits of the ADC output. These bits are undefined after a Reset.

Bit	Description (Continued)
[5:2] REFLVL	Internal Reference Voltage Level This reference is independent of the ADC voltage reference. Note: 8-pin devices contain two additional LSBs for increased resolution. For 20-/28-pin devices: 0000 = 0.0 V 0001 = 0.2 V 0010 = 0.4 V 0011 = 0.6 V 0100 = 0.8 V 0101 = 1.0 V (Default) 0110 = 1.2 V 0111 = 1.4 V 1000 = 1.6 V 1001 = 1.8 V 1010–1111 = Reserved

Byte Read

To read a byte from the NVDS array, user code must first push the address onto the stack. User code issues a CALL instruction to the address of the byte-read routine (0x1000). At the return from the sub-routine, the read byte resides in working register R0 and the read status byte resides in working register R1. The contents of the status byte are undefined for read operations to illegal addresses. Also, the user code must pop the address byte off the stack.

The read routine uses 9 bytes of stack space in addition to the one byte of address pushed by the user. Sufficient memory must be available for this stack usage.

Because of the Flash memory architecture, NVDS reads exhibit a nonuniform execution time. A read operation takes between 54 and 489 µs (assuming a 20 MHz system clock). Slower system clock speeds result in proportionally higher execution times.

NVDS byte reads from invalid addresses (those exceeding the NVDS array size) return 0xff. Illegal read operations have a 2 µs execution time.

The status byte returned by the NVDS read routine is zero for successful read, as determined by a CRC check. If the status byte is non-zero, there was a corrupted value in the NVDS array at the location being read. In this case, the value returned in R0 is the byte most recently written to the array that does not have a CRC error.

Power Failure Protection

The NVDS routines employ error checking mechanisms to ensure a power failure endangers only the most recently written byte. Bytes previously written to the array are not perturbed.

A system reset (such as a pin reset or Watchdog Timer reset) that occurs during a write operation also perturbs the byte currently being written. All other bytes in the array are unperturbed.

Optimizing NVDS Memory Usage for Execution Speed

NVDS read time can vary drastically. This discrepancy is a trade-off for minimizing the frequency of writes that require post-write page erases, as indicated in Table 107. The NVDS read time of address N is a function of the number of writes to addresses other than N since the most recent write to address N, or the number of writes since the most recent page erase. Neglecting effects caused by page erases and results caused by the initial condition in which the NVDS is blank, a rule of thumb is that every write since the most recent page erase causes read times of unwritten addresses to increase by 1 µs, up to a maximum of (511-NVDS_SIZE) µs.

When selecting a new clock source, the system clock oscillator failure detection circuitry and the Watchdog Timer oscillator failure detection circuitry must be disabled. If SOFEN and WOFEN are not disabled prior to a clock switch-over, it is possible to generate an interrupt for a failure of either oscillator. The failure detection circuitry can be enabled anytime after a successful write of OSCSEL in the OSCCTL Register.

The internal precision oscillator is enabled by default. If the user code changes to a different oscillator, it may be appropriate to disable the IPO for power savings. Disabling the IPO does not occur automatically.

Clock Failure Detection and Recovery

Should an oscillator or timer fail, there are methods of recovery, as this section describes.

System Clock Oscillator Failure

The Z8F04xA family devices can generate nonmaskable interrupt-like events when the primary oscillator fails. To maintain system function in this situation, the clock failure recovery circuitry automatically forces the Watchdog Timer oscillator to drive the system clock. The Watchdog Timer oscillator must be enabled to allow the recovery. Although this oscillator runs at a much slower speed than the original system clock, the CPU continues to operate, allowing execution of a clock failure vector and software routines that either remedy the oscillator failure or issue a failure alert. This automatic switch-over is not available if the Watchdog Timer is selected as the system clock oscillator. It is also unavailable if the Watchdog Timer oscillator is disabled, though it is not necessary to enable the Watchdog Timer reset function (see the Watchdog Timer chapter on page 93).

The primary oscillator failure detection circuitry asserts if the system clock frequency drops below 1 kHz ±50%. If an external signal is selected as the system oscillator, it is possible that a very slow but nonfailing clock can generate a failure condition. Under these conditions, do not enable the clock failure circuitry (SOFEN must be deasserted in the OSCCTL Register).

Watchdog Timer Failure

In the event of a Watchdog Timer oscillator failure, a similar nonmaskable interrupt-like event is issued. This event does not trigger an attendant clock switch-over, but alerts the CPU of the failure. After a Watchdog Timer failure, it is no longer possible to detect a primary oscillator failure. The failure detection circuitry does not function if the Watchdog Timer is used as the system clock oscillator or if the Watchdog Timer oscillator has been disabled. For either of these cases, it is necessary to disable the detection circuitry by deasserting the WDFEN bit of the OSCCTL Register.

The Watchdog Timer oscillator failure detection circuit counts system clocks while looking for a Watchdog Timer clock. The logic counts 8004 system clock cycles before determining that a failure has occurred. The system clock rate determines the speed at which

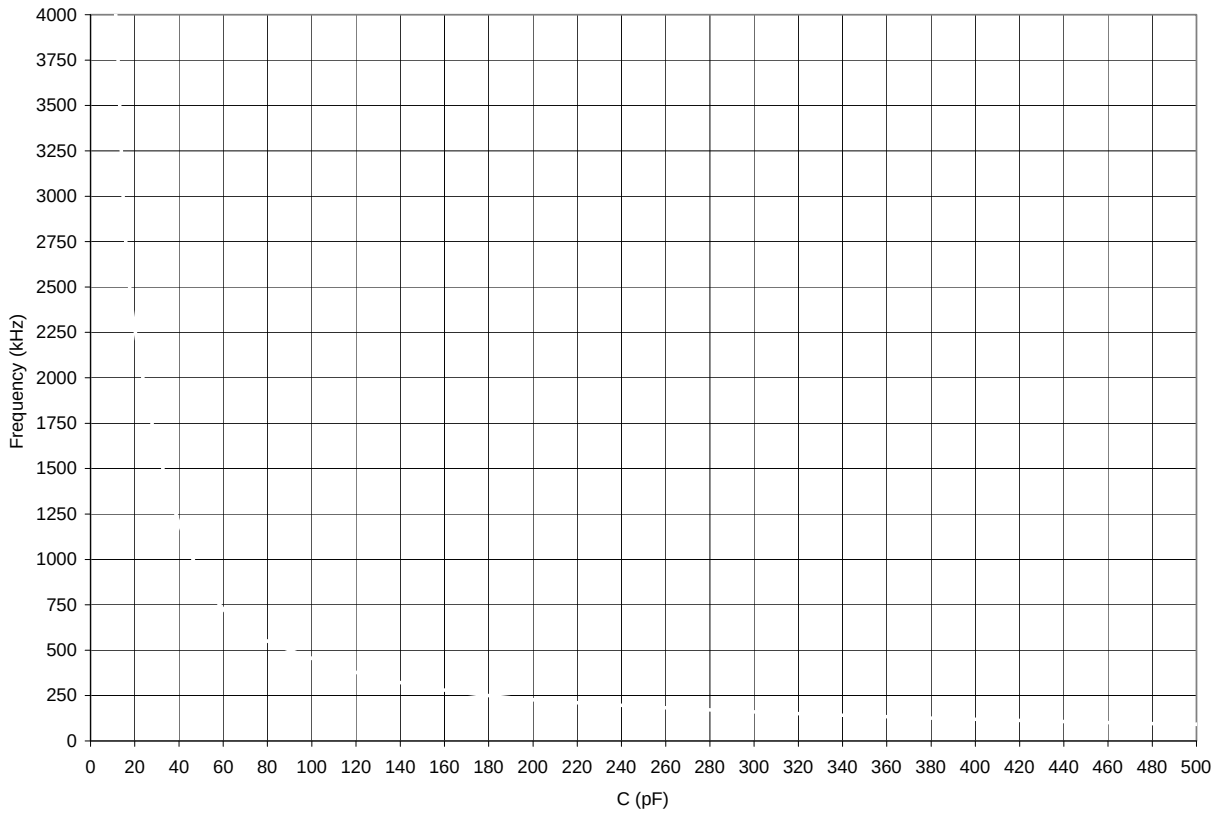

Figure 29. Typical RC Oscillator Frequency as a Function of the External Capacitance with a 45k : Resistor

! Caution: When using the external RC oscillator mode, the oscillator can stop oscillating if the power supply drops below 2.7V, but before the power supply drops to the Voltage Brown-Out threshold. The oscillator resumes oscillation when the supply voltage exceeds 2.7V.

On-Chip Debugger Timing

Figure 36 and Table 145 provide timing information for the DBG pin. The DBG pin timing specifications assume a 4ns maximum rise and fall time.

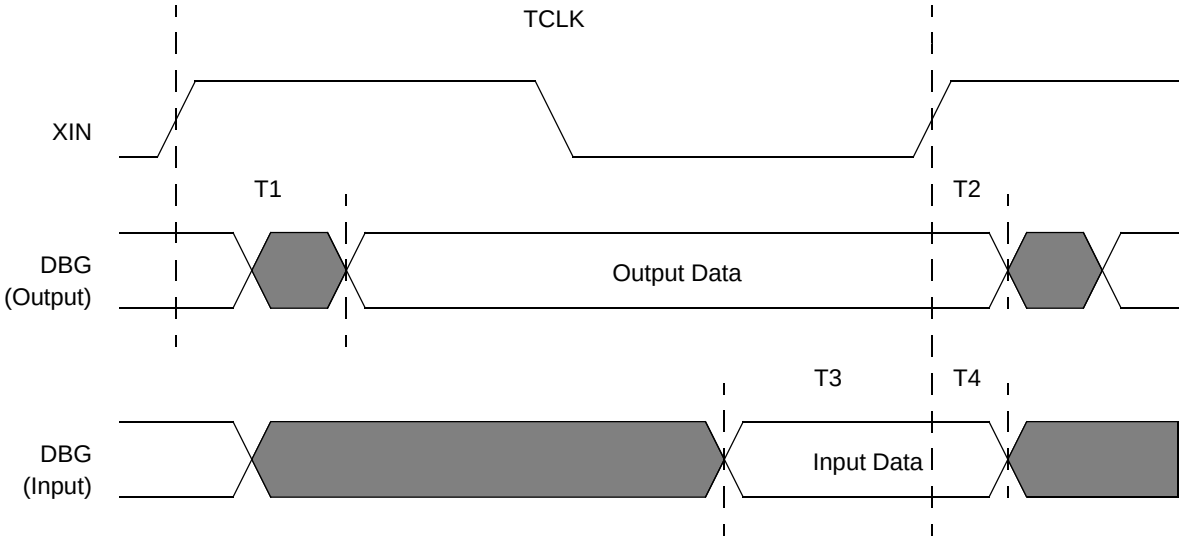

Figure 36. On-Chip Debugger Timing

Table 145. On-Chip Debugger Timing

		Delay (ns)	
Parameter	Abbreviation	Minimum	Maximum
DBG			
T_1	X_{IN} Rise to DBG Valid Delay	–	15
T_2	X_{IN} Rise to DBG Output Hold Time	2	–
T_3	DBG to XIN Rise Input Setup Time	5	–
T_4	DBG to XIN Rise Input Hold Time	5	–
