What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

1. All monitors that are active at power-up will gate the power up recovery and prevent exit from POWERUP phase until the minimum level is crossed. These monitors can in some cases be masked during normal device operation, but when active will always generate a destructive reset.
2. There is no voltage monitoring on the $V_{DD\_HV\_ADC0}$, $V_{DD\_HV\_ADC1}$, $V_{DD\_HV\_B}$ and $V_{DD\_HV\_C}$ I/O segments. For applications requiring monitoring of these segments, either connect these to $V_{DD\_HV\_A}$ at the PCB level or monitor externally.

6.2 Clocks and PLL interfaces modules

6.2.1 Main oscillator electrical characteristics

This device provides a driver for oscillator in pierce configuration with amplitude control. Controlling the amplitude allows a more sinusoidal oscillation, reducing in this way the EMI. Other benefits arises by reducing the power consumption. This Loop Controlled Pierce (LCP mode) requires good practices to reduce the stray capacitance of traces between crystal and MCU.

An operation in Full Swing Pierce (FSP mode), implemented by an inverter is also available in case of parasitic capacitances and cannot be reduced by using crystal with high equivalent series resistance. For this mode, a special care needs to be taken regarding the serial resistance used to avoid the crystal overdrive.

Other two modes called External (EXT Wave) and disable (OFF mode) are provided. For EXT Wave, the drive is disabled and an external source of clock within CMOS level based in analog oscillator supply can be used. When OFF, EXTAL is pulled down by 240 Kohms resistor and the feedback resistor remains active connecting XTAL through EXTAL by 1M resistor.

6.4.4 Ethernet switching specifications

The following timing specs are defined at the chip I/O pin and must be translated appropriately to arrive at timing specs/constraints for the physical interface.

6.4.4.1 MII signal switching specifications

The following timing specs meet the requirements for MII style interfaces for a range of transceiver devices.

NOTE

ENET0 supports the following xMII interfaces: MII, MII_Lite and RMII. ENET1 supports the following xMII interfaces: MII_Lite.

NOTE

It is only possible to use ENET0 and ENET1 simultaneously when both are configured for MII_Lite.

NOTE

In certain pinout configurations ENET1 MII-Lite signals can be across multiple VDD_HV_A/B/C domains. If these configuration are used, VDD_HV IO domains need to be at the same voltage (for example: 3.3V)

1. These specifications apply to JTAG boundary scan only.
2. This timing applies to TDI, TDO, TMS pins, however, actual frequency is limited by pad type for EXTEST instructions. Refer to pad specification for allowed transition frequency
3. Timing includes TCK pad delay, clock tree delay, logic delay and TDO output pad delay.
4. Applies to all pins, limited by pad slew rate. Refer to IO delay and transition specification and add 20 ns for JTAG delay.

Table 51. Nexus debug port timing [1] (continued)

No.	Symbol	Parameter	Conditions	Min	Max	Unit
9	t_{NTDIH}, t_{NTMSH}	TDI, TMS Data Hold Time	—	5	—	ns
10	t_{JOV}	TCK Low to TDO/RDY Data Valid	—	0	25	ns

1. JTAG specifications in this table apply when used for debug functionality. All Nexus timing relative to MCKO is measured from 50% of MCKO and 50% of the respective signal.
2. For all Nexus modes except DDR mode, MDO, $\overline{\text{MSEO}}$, and $\overline{\text{EVTO}}$ data is held valid until next MCKO low cycle.
3. The system clock frequency needs to be four times faster than the TCK frequency.

10.2 BAF execution duration

Following table specifies the typical BAF execution time in case BAF boot header is present at first location (Typical) and last location (worst case). Total Boot time is the sum of reset sequence duration and BAF execution time.

Table 55. BAF execution duration

BAF execution duration	Min	Typ	Max	Unit
BAF execution time (boot header at first location)	-	200	-	µs
BAF execution time (boot header at last location)	-	320	-	µs

10.3 Reset sequence description

The figures in this section show the internal states of the device during the five different reset sequences. The dotted lines in the figures indicate the starting point and the end point for which the duration is specified in Table 54.

With the beginning of DRUN mode, the first instruction is fetched and executed. At this point, application execution starts and the internal reset sequence is finished.

The following figures show the internal states of the device during the execution of the reset sequence and the possible states of the RESET_B signal pin.

NOTE

RESET_B is a bidirectional pin. The voltage level on this pin can either be driven low by an external reset generator or by the device internal reset circuitry. A high level on this pin can only be generated by an external pullup resistor which is strong enough to overdrive the weak internal pulldown resistor. The rising edge on RESET_B in the following figures indicates the time when the device stops driving it low. The reset sequence durations given in Table 54 are applicable only if the internal reset sequence is not prolonged by an external reset generator keeping RESET_B asserted low beyond the last Phase3.
