What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Functional operating conditions appear in the DC electrical characteristics. Absolute maximum ratings are stress ratings only, and functional operation at the maximum values is not guaranteed. See footnotes in Table 5 for specific conditions

Stress beyond the listed maximum values may affect device reliability or cause permanent damage to the device.

1. All monitors that are active at power-up will gate the power up recovery and prevent exit from POWERUP phase until the minimum level is crossed. These monitors can in some cases be masked during normal device operation, but when active will always generate a destructive reset.
2. There is no voltage monitoring on the $V_{DD\_HV\_ADC0}$, $V_{DD\_HV\_ADC1}$, $V_{DD\_HV\_B}$ and $V_{DD\_HV\_C}$ I/O segments. For applications requiring monitoring of these segments, either connect these to $V_{DD\_HV\_A}$ at the PCB level or monitor externally.

1. Active ADC input, VinA < [min(ADC_VrefH, ADC_ADV, VDD_HV_IOx)]. VDD_HV_IOx refers to I/O segment supply voltage. Violation of this condition would lead to degradation of ADC performance. Please refer to Table: 'Absolute maximum ratings' to avoid damage. Refer to Table: 'Recommended operating conditions (VDD_HV_x = 3.3 V)' for required relation between IO_supply_A,B,C and ADC_Supply.
2. The internally generated clock (known as AD_clk or ADCK) could be same as the peripheral clock or half of the peripheral clock based on register configuration in the ADC.
3. During the sample time the input capacitance C_S can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within t_{sample}. After the end of the sample time t_{sample}, changes of the analog input voltage have no effect on the conversion result. Values for the sample clock t_{sample} depend on programming.
4. This parameter does not include the sample time t_{sample}, but only the time for determining the digital result and the time to load the result register with the conversion result.
5. Apart from tsample and tconv, few cycles are used up in ADC digital interface and hence the overall throughput from the ADC is lower.
6. See Figure 2.
7. Current injection condition for ADC channels is defined for an inactive ADC channel (on which conversion is NOT being performed), and this occurs when voltage on the ADC pin exceeds the I/O supply or ground. However, absolute maximum voltage spec on pad input (VINA, see Table: Absolute maximum ratings) must be honored to meet TUE spec quoted here

10 Reset sequence

This section describes different reset sequences and details the duration for which the device remains in reset condition in each of those conditions.

10.1 Reset sequence duration

Table 54 specifies the minimum and the maximum reset sequence duration for the five different reset sequences described in Reset sequence description.

Table 54. RESET sequences

No.	Symbol	Parameter	T_{Reset}			Unit
			Min	Typ [1]	Max	
1	T_{DRB}	Destructive Reset Sequence, BIST enabled	5.730	7.796		ms
2	T_{DR}	Destructive Reset Sequence, BIST disabled	0.111	0.182		ms
3	T_{ERLB}	External Reset Sequence Long, Unsecure Boot	5.729	7.793		ms
4	T_{FRL}	Functional Reset Sequence Long, Unsecure Boot	0.110	0.179		ms
5	T_{FRS}	Functional Reset Sequence Short, Unsecure Boot	0.007	0.009		ms

1. The Typ value is applicable only if the reset sequence duration is not prolonged by an extended assertion of RESET_B by an external reset generator.

10.2 BAF execution duration

Following table specifies the typical BAF execution time in case BAF boot header is present at first location (Typical) and last location (worst case). Total Boot time is the sum of reset sequence duration and BAF execution time.

Table 55. BAF execution duration

BAF execution duration	Min	Typ	Max	Unit
BAF execution time (boot header at first location)	-	200	-	µs
BAF execution time (boot header at last location)	-	320	-	µs

10.3 Reset sequence description

The figures in this section show the internal states of the device during the five different reset sequences. The dotted lines in the figures indicate the starting point and the end point for which the duration is specified in Table 54.

With the beginning of DRUN mode, the first instruction is fetched and executed. At this point, application execution starts and the internal reset sequence is finished.

The following figures show the internal states of the device during the execution of the reset sequence and the possible states of the RESET_B signal pin.

NOTE

RESET_B is a bidirectional pin. The voltage level on this pin can either be driven low by an external reset generator or by the device internal reset circuitry. A high level on this pin can only be generated by an external pullup resistor which is strong enough to overdrive the weak internal pulldown resistor. The rising edge on RESET_B in the following figures indicates the time when the device stops driving it low. The reset sequence durations given in Table 54 are applicable only if the internal reset sequence is not prolonged by an external reset generator keeping RESET_B asserted low beyond the last Phase3.
