What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Symbol	Parameter	Conditions[1]	Min[2]	Max	Unit
T_A	Ambient temperature under bias	f_{CPU} ≤ 160 MHz	–40	125	°C
T_J	Junction temperature under bias	—	–40	150	°C

1. All voltages are referred to V_{SS_HV} unless otherwise specified
2. Device will be functional down (and electrical specifications as per various datasheet parameters will be guaranteed) to the point where one of the LVD/HVD resets the device. When voltage drops outside range for an LVD/HVD, device is reset.
3. VDD_HV_FLA must be connected to VDD_HV_A when VDD_HV_A = 3.3V

6. This supply is shorted VDD_HV_A on lower packages.

NOTE

If VDD_HV_A is in 5V range, it is necessary to use internal Flash supply 3.3V regulator. VDD_HV_FLA should not be supplied externally and should only have decoupling capacitor.

1. Active ADC input, VinA < [min(ADC_VrefH, ADC_ADV, VDD_HV_IOx)]. VDD_HV_IOx refers to I/O segment supply voltage. Violation of this condition would lead to degradation of ADC performance. Please refer to Table: 'Absolute maximum ratings' to avoid damage. Refer to Table: 'Recommended operating conditions (VDD_HV_x = 3.3 V)' for required relation between IO_supply_A,B,C and ADC_Supply.
2. The internally generated clock (known as AD_clk or ADCK) could be same as the peripheral clock or half of the peripheral clock based on register configuration in the ADC.
3. During the sample time the input capacitance C_S can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within t_{sample}. After the end of the sample time t_{sample}, changes of the analog input voltage have no effect on the conversion result. Values for the sample clock t_{sample} depend on programming.
4. This parameter does not include the sample time t_{sample}, but only the time for determining the digital result and the time to load the result register with the conversion result.
5. Apart from tsample and tconv, few cycles are used up in ADC digital interface and hence the overall throughput from the ADC is lower.
6. See Figure 2.
7. Current injection condition for ADC channels is defined for an inactive ADC channel (on which conversion is NOT being performed), and this occurs when voltage on the ADC pin exceeds the I/O supply or ground. However, absolute maximum voltage spec on pad input (VINA, see Table: Absolute maximum ratings) must be honored to meet TUE spec quoted here

10 Reset sequence

This section describes different reset sequences and details the duration for which the device remains in reset condition in each of those conditions.

10.1 Reset sequence duration

Table 54 specifies the minimum and the maximum reset sequence duration for the five different reset sequences described in Reset sequence description.

Table 54. RESET sequences

No.	Symbol	Parameter	T_{Reset}			Unit
			Min	Typ [1]	Max	
1	T_{DRB}	Destructive Reset Sequence, BIST enabled	5.730	7.796		ms
2	T_{DR}	Destructive Reset Sequence, BIST disabled	0.111	0.182		ms
3	T_{ERLB}	External Reset Sequence Long, Unsecure Boot	5.729	7.793		ms
4	T_{FRL}	Functional Reset Sequence Long, Unsecure Boot	0.110	0.179		ms
5	T_{FRS}	Functional Reset Sequence Short, Unsecure Boot	0.007	0.009		ms

1. The Typ value is applicable only if the reset sequence duration is not prolonged by an extended assertion of RESET_B by an external reset generator.

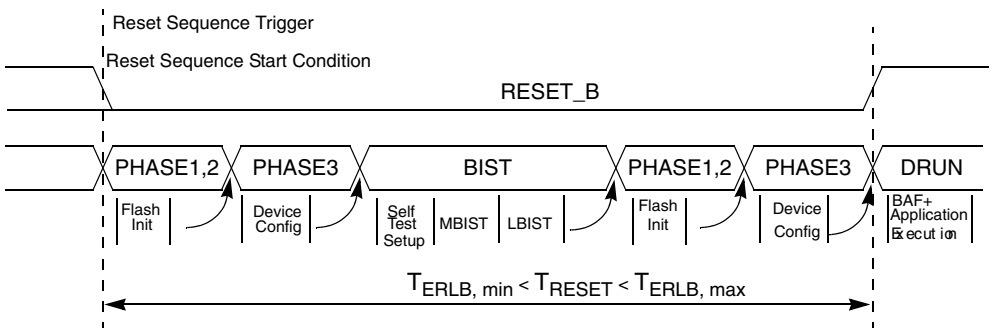

Figure 37. External reset sequence long, BIST enabled

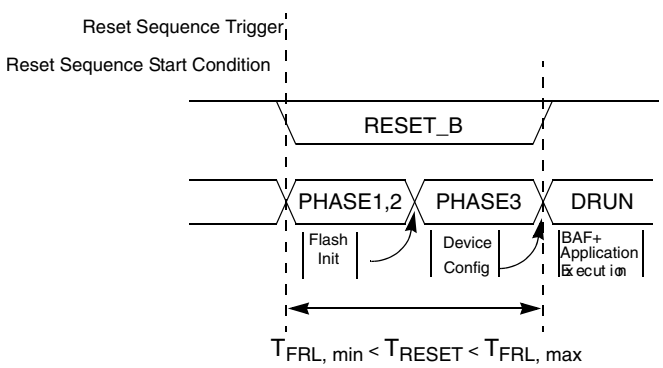

Figure 38. Functional reset sequence long

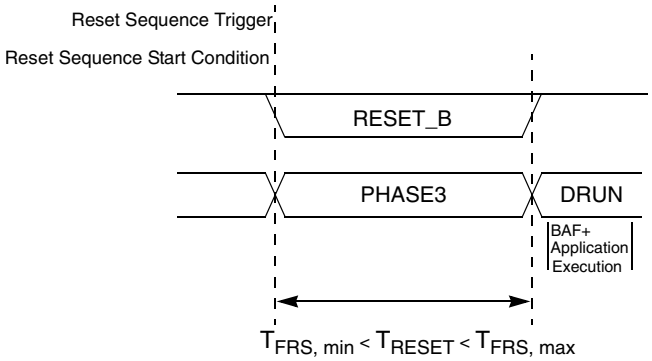

Figure 39. Functional reset sequence short

The reset sequences shown in Figure 38 and Figure 39 are triggered by functional reset events. RESET_B is driven low during these two reset sequences only if the corresponding functional reset source (which triggered the reset sequence) was enabled to drive RESET_B low for the duration of the internal reset sequence. See the RGM_FBRE register in the device reference manual for more information.
