E·XFL

Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

Details

Product Status	Not For New Designs
Core Processor	8051
Core Size	8-Bit
Speed	25MHz
Connectivity	SMBus (2-Wire/I ² C), SPI, UART/USART
Peripherals	Cap Sense, POR, PWM, WDT
Number of I/O	13
Program Memory Size	4KB (4K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	256 x 8
Voltage - Supply (Vcc/Vdd)	1.8V ~ 3.6V
Data Converters	-
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	16-SOIC (0.154", 3.90mm Width)
Supplier Device Package	16-SOIC
Purchase URL	https://www.e-xfl.com/product-detail/silicon-labs/c8051f833-gs

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

3. Pin Definitions

Name	Pin QSOP-24	Pin QFN-20	Pin SOIC-16	Туре	Description
GND	5	2	4		Ground. This ground connection is required. The center pad may optionally be connected to ground as well on the QFN-20 packages.
V _{DD}	6	3	5		Power Supply Voltage.
RST/	7	4	6	D I/O	Device Reset. Open-drain output of internal POR or V_{DD} monitor. An external source can initiate a system reset by driving this pin low for at least 10 μ s.
C2CK				D I/O	Clock signal for the C2 Debug Interface.
P2.0/	8	5	7	D I/O	Bi-directional data signal for the C2 Debug Inter- face. Shared with P2.0 on 20-pin packaging and P2.4 on 24-pin packaging.
C2D				D I/O	Bi-directional data signal for the C2 Debug Inter- face. Shared with P2.0 on 20-pin packaging and P2.4 on 24-pin packaging.
P0.0/	4	1	3	D I/O or A In	Port 0.0.
VREF				A In	External VREF input.
P0.1	3	20	2	D I/O or A In	Port 0.1.
P0.2/	2	19	1	D I/O or A In	Port 0.2.
XTAL1				A In	External Clock Input. This pin is the external oscillator return for a crystal or resonator.
P0.3/	23	18	16	D I/O or A In	Port 0.3.
XTAL2				A I/O or D In	External Clock Output. For an external crystal or resonator, this pin is the excitation driver. This pin is the external clock input for CMOS, capacitor, or RC oscillator configurations.
P0.4	22	17	15	D I/O or A In	Port 0.4.

Table 3.1. Pin Definitions for the C8051F80x-83x

Name	Pin QSOP-24	Pin QFN-20	Pin SOIC-16	Туре	Description
P0.5	21	16	14	D I/O or A In	Port 0.5.
P0.6/	20	15	13	D I/O or A In	Port 0.6.
CNVSTR				D In	ADC0 External Convert Start or IDA0 Update Source Input.
P0.7	19	14	12	D I/O or A In	Port 0.7.
P1.0	18	13	11	D I/O or A In	Port 1.0.
P1.1	17	12	10	D I/O or A In	Port 1.1.
P1.2	16	11	9	D I/O or A In	Port 1.2.
P1.3	15	10	8	D I/O or A In	Port 1.3.
P1.4	14	9		D I/O or A In	Port 1.4.
P1.5	11	8		D I/O or A In	Port 1.5.
P1.6	10	7		D I/O or A In	Port 1.6.
P1.7	9	6		D I/O or A In	Port 1.7.
NC	1, 12, 13, 24				No Connection.

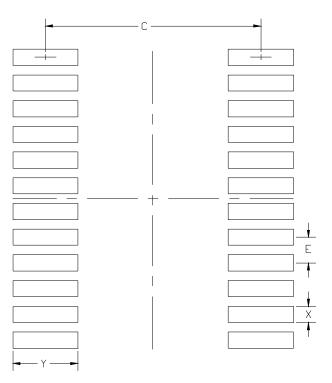

Figure 5.2. QSOP-24 PCB Land Pattern

Table 5.2. QSOP-24 PCB Land Pattern Dimensions

Dimension	Min	Мах
С	5.20	5.30
E	0.635	BSC
Х	0.30	0.40
Y	1.50	1.60

Notes: General

- 1. All dimensions shown are in millimeters (mm) unless otherwise noted.
- 2. This land pattern design is based on the IPC-7351 guidelines.

Solder Mask Design

3. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 μm minimum, all the way around the pad.

Stencil Design

- **4.** A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
- 5. The stencil thickness should be 0.125 mm (5 mils).
- 6. The ratio of stencil aperture to land pad size should be 1:1 for all perimeter pads.

Card Assembly

- 7. A No-Clean, Type-3 solder paste is recommended.
- 8. The recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for Small Body Components.

9. Temperature Sensor

An on-chip temperature sensor is included on the C8051F800/1/2/3/4/5, C8051F812/3/4/5/6/7, C8051F824/5/6, and C8051F830/1/2 which can be directly accessed via the ADC multiplexer in singleended configuration. To use the ADC to measure the temperature sensor, the ADC mux channel should be configured to connect to the temperature sensor. The temperature sensor transfer function is shown in Figure 9.1. The output voltage (V_{TEMP}) is the positive ADC input when the ADC multiplexer is set correctly. The TEMPE bit in register REF0CN enables/disables the temperature sensor, as described in SFR Definition 10.1. While disabled, the temperature sensor defaults to a high impedance state and any ADC measurements performed on the sensor will result in meaningless data. Refer to Table 7.11 for the slope and offset parameters of the temperature sensor.

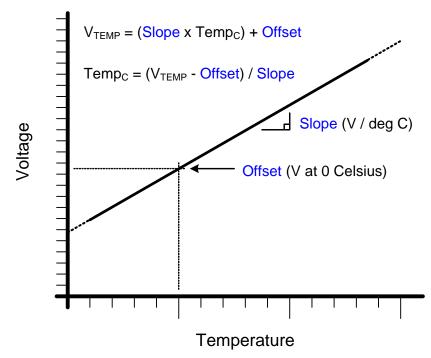

Figure 9.1. Temperature Sensor Transfer Function

9.1. Calibration

The uncalibrated temperature sensor output is extremely linear and suitable for relative temperature measurements (see Table 5.1 for linearity specifications). For absolute temperature measurements, offset and/or gain calibration is recommended. Typically a 1-point (offset) calibration includes the following steps:

- 1. Control/measure the ambient temperature (this temperature must be known).
- 2. Power the device, and delay for a few seconds to allow for self-heating.
- 3. Perform an ADC conversion with the temperature sensor selected as the ADC's input.
- 4. Calculate the offset characteristics, and store this value in non-volatile memory for use with subsequent temperature sensor measurements.

Figure 5.3 shows the typical temperature sensor error assuming a 1-point calibration at 0 °C.

Parameters that affect ADC measurement, in particular the voltage reference value, will also affect temperature measurement.

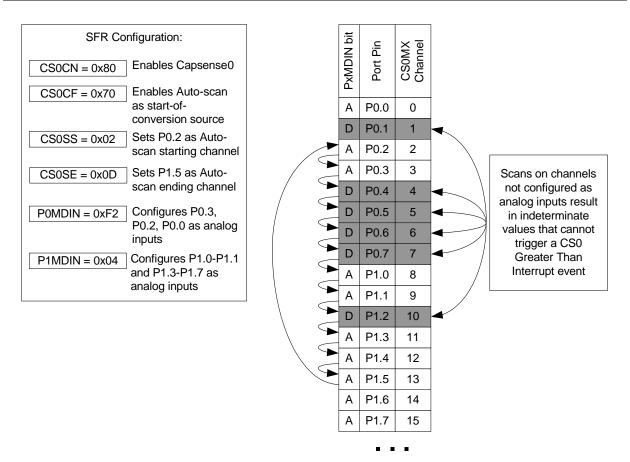

Figure 13.2. Auto-Scan Example

13.4. CS0 Comparator

The CS0 comparator compares the latest capacitive sense conversion result with the value stored in CS0THH:CS0THL. If the result is less than or equal to the stored value, the CS0CMPF bit(CS0CN:0) is set to 0. If the result is greater than the stored value, CS0CMPF is set to 1.

If the CS0 conversion accumulator is configured to accumulate multiple conversions, a comparison will not be made until the last conversion has been accumulated.

An interrupt will be generated if CS0 greater-than comparator interrupts are enabled by setting the ECS-GRT bit (EIE2.1) when the comparator sets CS0CMPF to 1.

If auto-scan is running when the comparator sets the CS0CMPF bit, no further auto-scan initiated conversions will start until firmware sets CS0BUSY to 1.

A CS0 greater-than comparator event can wake a device from suspend mode. This feature is useful in systems configured to continuously sample one or more capacitive sense channels. The device will remain in the low-power suspend state until the captured value of one of the scanned channels causes a CS0 greater-than comparator event to occur. It is not necessary to have CS0 comparator interrupts enabled in order to wake a device from suspend with a greater-than event.

Note: On waking from suspend mode due to a CS0 greater-than comparator event, the CS0CN register should be accessed only after at least two system clock cycles have elapsed.

For a summary of behavior with different CS0 comparator, auto-scan, and auto accumulator settings, please see Table 13.1.

Mnemonic Description		Bytes	Clock Cycles
ANL C, bit	AND direct bit to Carry	2	2
ANL C, /bit	AND complement of direct bit to Carry	2	2
ORL C, bit	OR direct bit to carry	2	2

		This bit sets the priority of the Capacitive Sense Greater Than Comparator interrupt.0: CS0 Greater Than Comparator interrupt set to low priority level.1: CS0 Greater Than Comparator set to high priority level.
0	PSCCPT	 Capacitive Sense Conversion Complete Priority Control. This bit sets the priority of the Capacitive Sense Conversion Complete interrupt. 0: CS0 Conversion Complete set to low priority level. 1: CS0 Conversion Complete set to high priority level.

23.4. Port I/O Initialization

Port I/O initialization consists of the following steps:

- 1. Select the input mode (analog or digital) for all Port pins, using the Port Input Mode register (PnMDIN). If the pin is in analog mode, a '1' must also be written to the corresponding Port Latch (Pn).
- 2. Select the output mode (open-drain or push-pull) for all Port pins, using the Port Output Mode register (PnMDOUT).
- 3. Select any pins to be skipped by the I/O Crossbar using the Port Skip registers (PnSKIP).
- 4. Assign Port pins to desired peripherals (XBR0, XBR1).
- 5. Enable the Crossbar (XBARE = 1).

All Port pins must be configured as either analog or digital inputs. When a pin is configured as an analog input, its weak pullup, digital driver, and digital receiver are disabled. This process saves power and reduces noise on the analog input. Pins configured as digital inputs may still be used by analog peripherals; however this practice is not recommended.

Additionally, all analog input pins should be configured to be skipped by the Crossbar (accomplished by setting the associated bits in PnSKIP). Port input mode is set in the PnMDIN register, where a 1 indicates a digital input, and a 0 indicates an analog input. All port pins in analog mode must have a '1' set in the corresponding Port Latch register. All pins default to digital inputs on reset. See SFR Definition 23.8 and SFR Definition 23.12 for the PnMDIN register details.

The output driver characteristics of the I/O pins are defined using the Port Output Mode registers (PnMD-OUT). Each Port Output driver can be configured as either open drain or push-pull. This selection is required even for the digital resources selected in the XBRn registers, and is not automatic. The only exception to this is the SMBus (SDA, SCL) pins, which are configured as open-drain regardless of the PnMDOUT settings. When the WEAKPUD bit in XBR1 is 0, a weak pullup is enabled for all Port I/O configured as open-drain. WEAKPUD does not affect the push-pull Port I/O. Furthermore, the weak pullup is turned off on an output that is driving a 0 to avoid unnecessary power dissipation.

Registers XBR0 and XBR1 must be loaded with the appropriate values to select the digital I/O functions required by the design. Setting the XBARE bit in XBR1 to 1 enables the Crossbar. Until the Crossbar is enabled, the external pins remain as standard Port I/O (in input mode), regardless of the XBRn Register settings. For given XBRn Register settings, one can determine the I/O pin-out using the Priority Decode Table; as an alternative, the Configuration Wizard utility will determine the Port I/O pin-assignments based on the XBRn Register settings.

The Crossbar must be enabled to use Port pins as standard Port I/O in output mode. Port output drivers are disabled while the Crossbar is disabled.

24.2. 32-bit CRC Algorithm

The C8051F80x-83x CRC unit calculates the 32-bit CRC using a poly of 0x04C11DB7. The CRC-32 algorithm is "reflected", meaning that all of the input bytes and the final 32-bit output are bit-reversed in the processing engine. The following is a description of a simplified CRC algorithm that produces results identical to the hardware:

- 1. XOR the least-significant byte of the current CRC result with the input byte. If this is the first iteration of the CRC unit, the current CRC result will be the set initial value (0x00000000 or 0xFFFFFFF).
- 2. Right-shift the CRC result.
- 3. If the LSB of the CRC result is set, XOR the CRC result with the reflected polynomial (0xEDB88320).
- 4. Repeat at Step 2 for the number of input bits (8).

For example, the 32-bit C8051F80x-83x CRC algorithm can be described by the following code:

```
unsigned long UpdateCRC (unsigned long CRC_acc, unsigned char CRC_input) {
   unsigned char i; // loop counter
   #define POLY 0xEDB88320 // bit-reversed version of the poly 0x04C11DB7
   // Create the CRC "dividend" for polynomial arithmetic (binary arithmetic
   // with no carries)
   CRC_acc = CRC_acc ^ CRC_input;
   // "Divide" the poly into the dividend using CRC XOR subtraction
   // CRC_acc holds the "remainder" of each divide
   // Only complete this division for 8 bits since input is 1 byte
   for (i = 0; i < 8; i++)
   {
      // Check if the MSB is set (if MSB is 1, then the POLY can "divide" \,
      // into the "dividend")
      if ((CRC_acc & 0x0000001) == 0x0000001)
      {
          // if so, shift the CRC value, and XOR "subtract" the poly
          CRC_acc = CRC_acc >> 1;
          CRC_acc ^= POLY;
      }
      else
      {
          // if not, just shift the CRC value
          CRC_acc = CRC_acc >> 1;
      }
   }
   return CRC_acc; // Return the final remainder (CRC value)
```

Table 24.2 lists example input values and the associated outputs using the 32-bit C8051F80x-83x CRC algorithm (an initial value of 0xFFFFFFF is used):

Table 24.2. Example 32-bit CRC Outputs

Input	Output
0x63	0xF9462090
0xAA, 0xBB, 0xCC	0x41B207B3
0x00, 0x00, 0xAA, 0xBB, 0xCC	0x78D129BC

Parameter	Description	Min	Max	Units

Note: T _{SYSCL}	K is equal to one period of the device system clock (S	YSCLK).		I

Table 25.1. SPI Slave Timing Parameters

26.4.2. SMB0CN Control Register

SMB0CN is used to control the interface and to provide status information (see SFR Definition 26.2). The higher four bits of SMB0CN (MASTER, TXMODE, STA, and STO) form a status vector that can be used to jump to service routines. MASTER indicates whether a device is the master or slave during the current transfer. TXMODE indicates whether the device is transmitting or receiving data for the current byte.

STA and STO indicate that a START and/or STOP has been detected or generated since the last SMBus interrupt. STA and STO are also used to generate START and STOP conditions when operating as a master. Writing a 1 to STA will cause the SMBus interface to enter Master Mode and generate a START when the bus becomes free (STA is not cleared by hardware after the START is generated). Writing a 1 to STO while in Master Mode will cause the interface to generate a STOP and end the current transfer after the next ACK cycle. If STO and STA are both set (while in Master Mode), a STOP followed by a START will be generated.

The ARBLOST bit indicates that the interface has lost an arbitration. This may occur anytime the interface is transmitting (master or slave). A lost arbitration while operating as a slave indicates a bus error condition. ARBLOST is cleared by hardware each time SI is cleared.

The SI bit (SMBus Interrupt Flag) is set at the beginning and end of each transfer, after each byte frame, or when an arbitration is lost; see Table 26.3 for more details.

Important Note About the SI Bit: The SMBus interface is stalled while SI is set; thus SCL is held low, and the bus is stalled until software clears SI.

26.4.2.1. Software ACK Generation

When the EHACK bit in register SMB0ADM is cleared to 0, the firmware on the device must detect incoming slave addresses and ACK or NACK the slave address and incoming data bytes. As a receiver, writing the ACK bit defines the outgoing ACK value; as a transmitter, reading the ACK bit indicates the value received during the last ACK cycle. ACKRQ is set each time a byte is received, indicating that an outgoing ACK value is needed. When ACKRQ is set, software should write the desired outgoing value to the ACK bit before clearing SI. A NACK will be generated if software does not write the ACK bit before clearing SI. SDA will reflect the defined ACK value immediately following a write to the ACK bit; however SCL will remain low until SI is cleared. If a received slave address is not acknowledged, further slave events will be ignored until the next START is detected.

26.4.2.2. Hardware ACK Generation

When the EHACK bit in register SMB0ADM is set to 1, automatic slave address recognition and ACK generation is enabled. More detail about automatic slave address recognition can be found in Section 26.4.3. As a receiver, the value currently specified by the ACK bit will be automatically sent on the bus during the ACK cycle of an incoming data byte. As a transmitter, reading the ACK bit indicates the value received on the last ACK cycle. The ACKRQ bit is not used when hardware ACK generation is enabled. If a received slave address is NACKed by hardware, further slave events will be ignored until the next START is detected, and no interrupt will be generated.

Table 26.3 lists all sources for hardware changes to the SMB0CN bits. Refer to Table 26.5 for SMBus status decoding using the SMB0CN register.

SFR Definition 28.1. CKCON: Clock Control

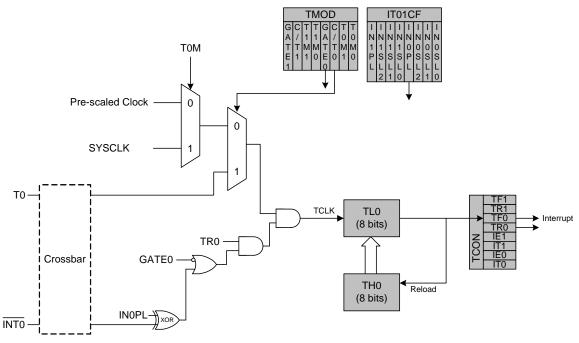

Figure 28.2. T0 Mode 2 Block Diagram

28.1.4. Mode 3: Two 8-bit Counter/Timers (Timer 0 Only)

In Mode 3, Timer 0 is configured as two separate 8-bit counter/timers held in TL0 and TH0. The counter/timer in TL0 is controlled using the Timer 0 control/status bits in TCON and TMOD: TR0, C/T0, GATE0 and TF0. TL0 can use either the system clock or an external input signal as its timebase. The TH0 register is restricted to a timer function sourced by the system clock or prescaled clock. TH0 is enabled using the Timer 1 run control bit TR1. TH0 sets the Timer 1 overflow flag TF1 on overflow and thus controls the Timer 1 interrupt.

Timer 1 is inactive in Mode 3. When Timer 0 is operating in Mode 3, Timer 1 can be operated in Modes 0, 1 or 2, but cannot be clocked by external signals nor set the TF1 flag and generate an interrupt. However, the Timer 1 overflow can be used to generate baud rates or overflow conditions for other peripherals. While Timer 0 is operating in Mode 3, Timer 1 run control is handled through its mode settings. To run Timer 1 while Timer 0 is in Mode 3, set the Timer 1 Mode as 0, 1, or 2. To disable Timer 1, configure it for Mode 3.

28.2.2. 8-bit Timers with Auto-Reload

When T2SPLIT is set, Timer 2 operates as two 8-bit timers (TMR2H and TMR2L). Both 8-bit timers operate in auto-reload mode as shown in Figure 28.5. TMR2RLL holds the reload value for TMR2L; TMR2RLH holds the reload value for TMR2H. The TR2 bit in TMR2CN handles the run control for TMR2H. TMR2L is always running when configured for 8-bit Mode. Timer 2 can also be used in capture mode to capture rising edges of the Comparator 0 output.

Each 8-bit timer may be configured to use SYSCLK, SYSCLK divided by 12, or the external oscillator clock source divided by 8. The Timer 2 Clock Select bits (T2MH and T2ML in CKCON) select either SYSCLK or the clock defined by the Timer 2 External Clock Select bit (T2XCLK in TMR2CN), as follows:

T2MH	T2XCLK	TMR2H Clock Source
0	0	SYSCLK / 12
0	1	External Clock / 8
1	Х	SYSCLK

T2ML	T2XCLK	TMR2L Clock Source
0	0	SYSCLK / 12
0	1	External Clock / 8
1	Х	SYSCLK

The TF2H bit is set when TMR2H overflows from 0xFF to 0x00; the TF2L bit is set when TMR2L overflows from 0xFF to 0x00. When Timer 2 interrupts are enabled (IE.5), an interrupt is generated each time TMR2H overflows. If Timer 2 interrupts are enabled and TF2LEN (TMR2CN.5) is set, an interrupt is generated each time either TMR2L or TMR2H overflows. When TF2LEN is enabled, software must check the TF2H and TF2L flags to determine the source of the Timer 2 interrupt. The TF2H and TF2L interrupt flags are not cleared by hardware and must be manually cleared by software.

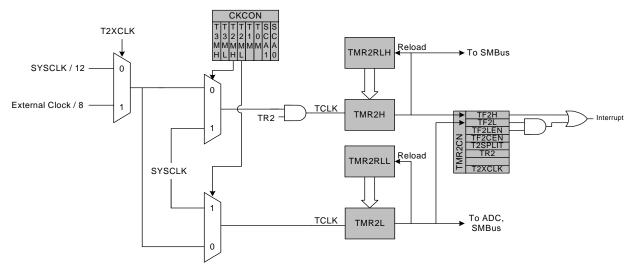

Figure 28.5. Timer 2 8-Bit Mode Block Diagram

28.2.3. Comparator 0 Capture Mode

The capture mode in Timer 2 allows Comparator 0 rising edges to be captured with the timer clocking from the system clock or the system clock divided by 12. Timer 2 capture mode is enabled by setting TF2CEN to 1 and T2SPLIT to 0.

When capture mode is enabled, a capture event will be generated on every Comparator 0 rising edge. When the capture event occurs, the contents of Timer 2 (TMR2H:TMR2L) are loaded into the Timer 2 reload registers (TMR2RLH:TMR2RLL) and the TF2H flag is set (triggering an interrupt if Timer 2 interrupts are enabled). By recording the difference between two successive timer capture values, the Comparator 0 period can be determined with respect to the Timer 2 clock. The Timer 2 clock should be much faster than the capture clock to achieve an accurate reading.

This mode allows software to determine the time between consecutive Comparator 0 rising edges, which can be used for detecting changes in the capacitance of a capacitive switch, or measuring the frequency of a low-level analog signal.

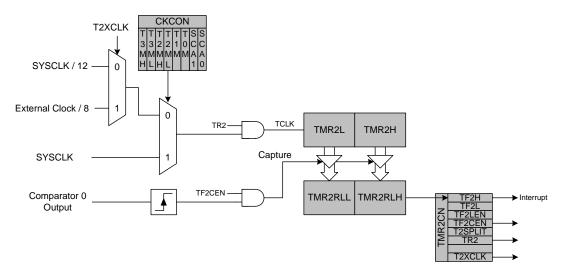

Figure 28.6. Timer 2 Capture Mode Block Diagram

29.2. PCA0 Interrupt Sources

Figure 29.3 shows a diagram of the PCA interrupt tree. There are five independent event flags that can be used to generate a PCA0 interrupt. They are: the main PCA counter overflow flag (CF), which is set upon a 16-bit overflow of the PCA0 counter, an intermediate overflow flag (COVF), which can be set on an overflow from the 8th through 15th bit of the PCA0 counter, and the individual flags for each PCA channel (CCF0, CCF1, and CCF2), which are set according to the operation mode of that module. These event flags are always set when the trigger condition occurs. Each of these flags can be individually selected to generate a PCA0 interrupt, using the corresponding interrupt enable flag (ECF for CF, ECOV for COVF, and ECCFn for each CCFn). PCA0 interrupts must be globally enabled before any individual interrupt sources are recognized by the processor. PCA0 interrupts are globally enabled by setting the EA bit in the IE register and the EPCA0 bit in the EIE1 register to logic 1.
