### What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

### Applications of "[Embedded - Microcontrollers](#)"

#### Details

Product Status	Obsolete
Core Processor	Z8
Core Size	8-Bit
Speed	25MHz
Connectivity	EBI/EMI, UART/USART
Peripherals	-
Number of I/O	24
Program Memory Size	-
Program Memory Type	ROMless
EEPROM Size	-
RAM Size	236 x 8
Voltage - Supply (Vcc/Vdd)	3V ~ 5.5V
Data Converters	-
Oscillator Type	Internal
Operating Temperature	0°C ~ 70°C (TA)
Mounting Type	Surface Mount
Package / Case	44-LCC (J-Lead)
Supplier Device Package	-
Purchase URL	<a href="https://www.e-xfl.com/product-detail/zilog/z86c9325vsc00tr">https://www.e-xfl.com/product-detail/zilog/z86c9325vsc00tr</a>

## Z86C93

### CMOS Z8® MULTIPLY/DIVIDE MICROCONTROLLER

---

#### FEATURES

- Complete microcontroller, up to 24 I/O lines, and up to 64 Kbytes of addressable external space each for program and data memory.
- 16-bit x 16-bit hardwired multiplier with 32-bit product in 17 clock cycles.
- 32-bit x 16-bit hardwired divider with 16-bit quotient and 16-bit remainder in 20 clock cycles.
- 256-byte register file, including 236 general-purpose registers, up to three I/O port registers and 16 status and control registers.
- 17-byte Expanded Register File, including two general-purpose registers and 15 status and control registers.
- Vectored, priority interrupts for I/O, counter/timers and UART.
- On-chip oscillator that accepts crystal or external clock drive.
- Two 16-bit counter timers with 6-bit prescalers.
- Third 16-bit counter/timer with 4-bit prescaler, one capture register and a fast decrement mode.
- Register Pointer for short, fast instructions that can access any one of the sixteen working register groups.
- Additional emulation signals SCLK, IACK, and /SYNC are made available.
- Two low power standby modes, STOP and HALT
- Full-duplex UART
- $3.3 \pm 10\%$  volt operation at 25 MHz
- $5.0 \pm 10\%$  volt operation at 20, 25 and 33 MHz

---

#### GENERAL DESCRIPTION

The Z86C93 is a CMOS ROMless Z8 microcontroller enhanced with a hardwired 16-bit x 16-bit multiplier and 32-bit/16-bit divider and three 16-bit counter timers (Figure 1). A capture register and a fast decrement mode is also provided. It is offered in 40-pin PDIP, 44-pin PLCC, 44-pin QFP and 48-pin VQFP (Figures 2, 3, 4, 5 and 6). Besides the four additional signals (SCLK, IACK, /SYNC and /WAIT), the Z86C93 is compatible with the Z86C91, yet it offers a much more powerful mathematical capability.

The Z86C93 provides up to 16 output address lines permitting an address space of up to 64 Kbytes of data and program memory each. Eight address outputs (AD7-AD0) are provided by a multiplexed, 8-bit, Address/Data bus. The remaining 8 bits can be provided by the software configuration of Port 0 to output address bits A15-A8.

**Figure 6. 48-Pin VQFP Package**

## PIN FUNCTIONS (Continued)

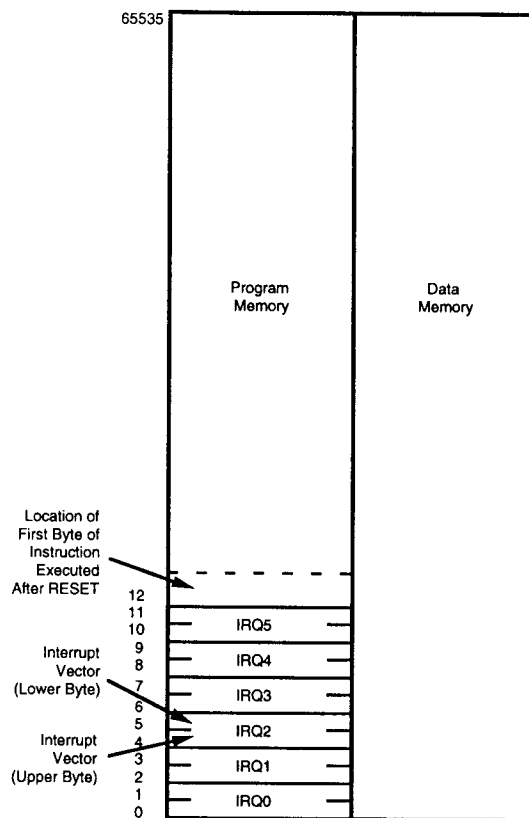

Figure 11. Serial Data Formats

## ADDRESS SPACE

**Program Memory.** The Z86C93 can address up to 64 Kbytes of external program memory. Program execution begins at external location 000CH after a reset.

**Data Memory.** The Z96C93 can address up to 64 Kbytes of external data memory. External data memory is included with, or separated from, the external program memory

space. /DM, an optional I/O function that can be programmed to appear on pin P34 is used to distinguish between data and program memory space (Figure 12). The state of the /DM signal is controlled by the type instruction being executed. An LDC opcode references PROGRAM (/DM inactive) memory, and an LDE instruction references DATA (/DM active Low) memory.

**Figure 12. Program and Data Memory Configuration**

**Expanded Register File.** The register file has been expanded to allow for additional system control registers, and for mapping of additional peripheral devices along with I/O ports into the register address area (Figure 13). The Z8 register address space R0 through R15 has now been implemented as 16 groups of 16 registers per group. These register groups are known as the ERF (Expanded Register File). Bits 7-4 of register RP select the working register group. Bits 3-0 of register RP select the expanded register group (Figure 14). The registers that are used in the multiply/divide unit reside in the Expanded Register File at Bank E and those for the additional timer control words reside in Bank D. The rest of the Expanded Register is not physically implemented and is open for future expansion.

**Register File.** The Register File consists of four I/O port registers, 236 general-purpose registers and 16 control

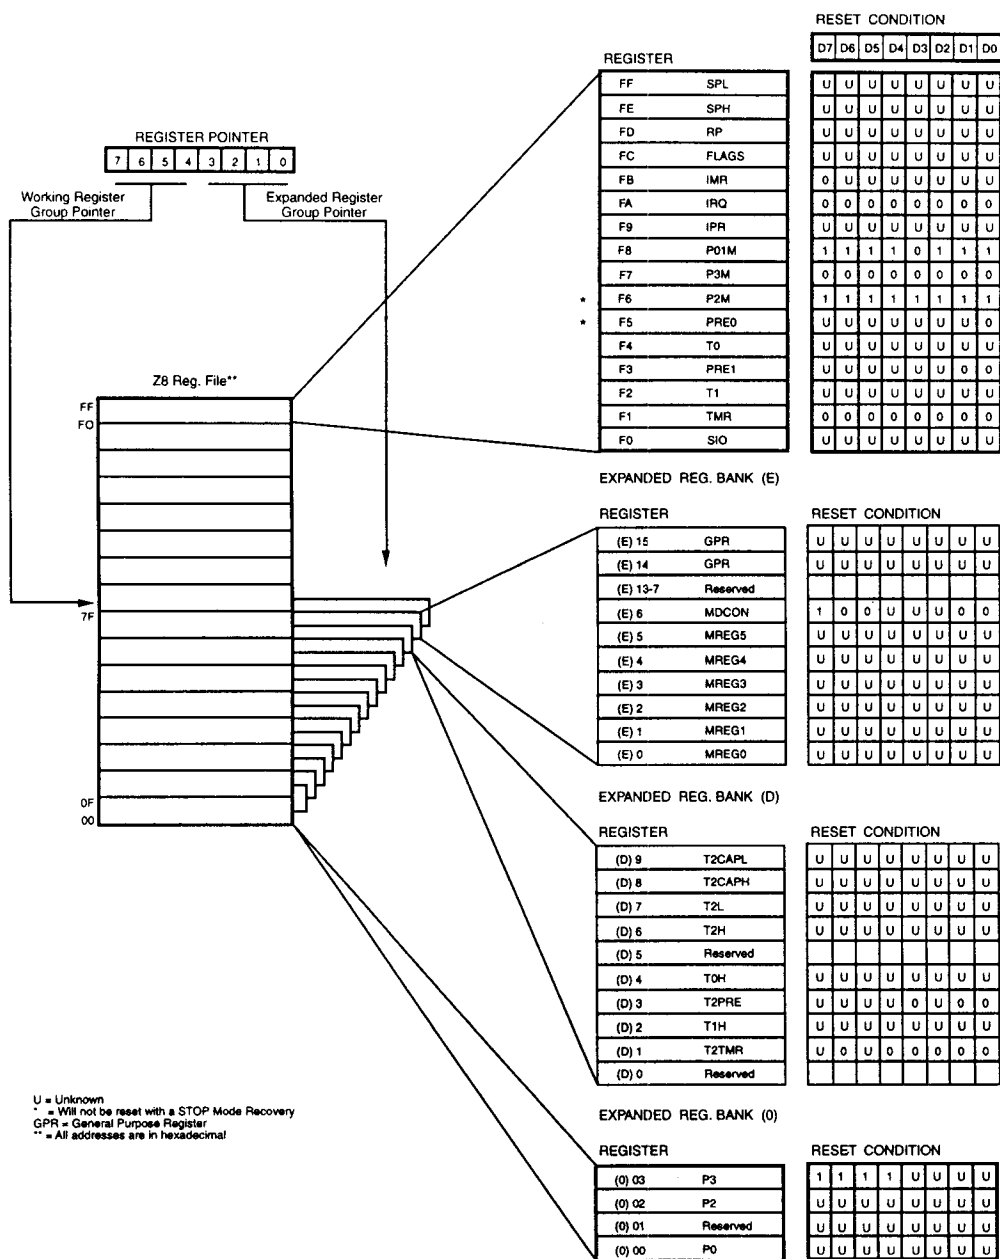

and status registers. The instructions can access registers directly or indirectly via an 8-bit address field. The Z86C93 also allows short 4-bit register addressing using the Register Pointer (Figure 15). In the 4-bit mode, the Register File is divided into 16 working register groups, each occupying 16 continuous locations. The Register Pointer addresses the starting location of the active working-register group.

**Note:** Register Group E0-EF can only be accessed through working registers and indirect addressing modes.

**Stack.** The Z86C93 has a 16-bit Stack Pointer (R254-R255), used for external stack, that resides anywhere in the data memory. An 8-bit Stack Pointer (R255) is used for the internal stack that resides within the 236 general-purpose registers (R4-R239). The high byte of the Stack Pointer (SPH, Bits 8-15) can be used as a general-purpose register when using internal stack only.

\_\_\_\_\_

## Z8 STANDARD CONTROL REGISTERS

### Figure 13. Register File

## FUNCTIONAL DESCRIPTION

This section breaks down the Z86C93 into its main functional parts.

### Multiply/Divide Unit

The Multiply/Divide unit describes the basic features, implementation details of the interface between the Z8 and the multiply/divide unit.

Basic features:

- 16-bit by 16-bit multiply with 32-bit product
- 32-bit by 16-bit divide with 16-bit quotient and 16-bit remainder
- Unsigned integer data format
- Simple interface to Z8

**Interface to Z8.** The following is a brief description of the register mapping in the multiply/divide unit and its interface to the Z8 (Figure 16).

The multiply/divide unit is interfaced like a peripheral. The only addressing mode available with the peripheral interface is register addressing. In other words, all of the operands are in the respective registers before a multiplication/division can start.

**Register mapping.** The registers used in the multiply/divide unit are mapped onto the expanded register file in Bank E. The exact register locations used are shown below.

REGISTER	ADDRESS
MREG0	(E) 00
MREG1	(E) 01
MREG2	(E) 02
MREG3	(E) 03
MREG4	(E) 04
MREG5	(E) 05
MDCON	(E) 06
GPR	(E) 14
GPR	(E) 15

Figure 16. Multiply/Divide Unit Block Diagram

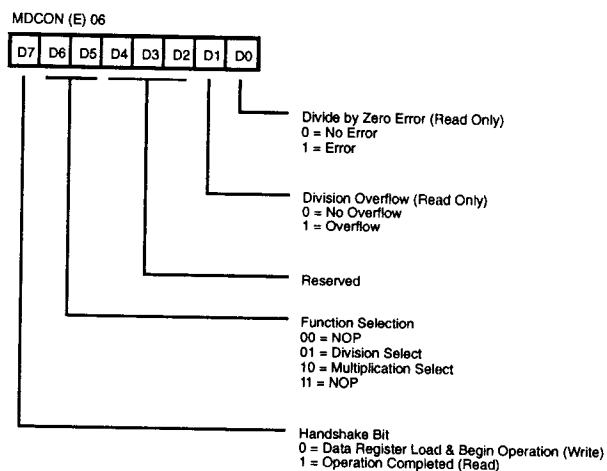

**Register allocation.** The following is the register allocation during multiplication.

Multiplier high byte	MREG2
Multiplier low byte	MREG3
Multiplicand high byte	MREG4
Multiplicand low byte	MREG5
Result high byte of high word	MREG0
Result low byte of high word	MREG1
Result high byte of low word	MREG2
Result low byte of low word	MREG3
Multiply/Divide Control register	MDCON

The following is the register allocation during division.

High byte of high word of dividend	MREG0
Low byte of high word of dividend	MREG1
High byte of low word of dividend	MREG2
Low byte of low word of dividend	MREG3
High byte of divisor	MREG4
Low byte of divisor	MREG5
High byte of remainder	MREG0
Low byte of remainder	MREG1
High byte of quotient	MREG2
Low byte of quotient	MREG3
Multiply/Divide Control register	MDCON

**Figure 17. Multiply/Divide Control Register (MDCON)**

**Control register.** The MDCON (Multiply/Divide Control Register) is used to interface with the multiply/divide unit (Figure 16). Specific functions of various bits in the control register are given below.

**DONE bit (D7).** This bit is a handshake bit between the math unit and the external world. On power up, this bit is set to 1 to indicate that the math unit has completed the previous operation and is ready to perform the next operation.

Before starting a new multiply/divide operation, this bit should be reset to 0 by the processor/programmer. This indicates that all the data registers have been loaded and the math unit can now begin a multiply/divide operation. During the process of multiplication or division, this bit is write-protected. Once the math unit completes its operation it sets this bit to indicate the completion of operation. The processor/programmer can then read the result.

**MULSL. Multiply Select (D6).** If this bit is set to 1, it indicates a multiply operation directive. Like the DONE bit, this bit is also write-protected during math unit operation and is reset to 0 by the math unit upon starting of the multiply/divide operation.

**DIVSL. Division Select (D5).** Similar to D6, D5 starts a division operation.

**D4-D2. Reserved.**

**DIVOVF. Division Overflow (D1).** This bit indicates an overflow during the division process. Division overflow occurs when the high word of the dividend is greater than or equal to the divisor. This bit is read only. When set to 1, it indicates overflow error.

---

## FUNCTIONAL DESCRIPTION (Continued)

**DIVZR. Division by Zero (D0).** When set to 1, this indicates an error of division by 0. This bit is read only.

Example:

Upon reset, the status of the MDCON register is 100uuu00b (D7 to D0).

u = Undefined  
x = Irrelevant  
b = Binary

If multiplication operation is desired, the MDCON register is set to 010xxxxb.

If the MDCON register is READ during multiplication, it would have a value of 000uuu00b.

Upon completion of multiplication, the result of the MDCON register is 100uuu00b.

If division operation is desired, the MDCON register is set to 001xxxxb.

During division operation, the register would contain 000uu??b (? - value depends on the DIVIDEND, DIVISOR).

Upon completion of division operation, the MDCON register contains 100uuu??b.

Note that once the multiplication/division operation starts, all data registers (MREG5 through MREG0) are write-protected and so are the writable bits of the MDCON register. The write protection is released once the math unit operation is complete. However, the registers may be read at any time.

A multiplication sequence would look like:

1. Load multiplier and multiplicand.
2. Load MDCON register to start multiply operation.
3. Wait for the DONE bit of the MDCON register to be set to 1 and then read results.

Note that while the multiply/divide operation is in progress, the programmer can use the Z8 to do other things. Also, since the multiplication/division takes a fixed number of cycles, he can start reading the results before the DONE bit is set.

During a division operation, the error flag bits are set at the beginning of the division operation which means the flag bits can be checked by the Z8 while the division operation is being done.

The two general purpose registers can be used as scratch pad registers or as external data memory address pointers during an LDE instruction. MREG0 through MREG5, if not used for multiplication or division, can be used as general purpose registers.

**Performance of multiplication.** The actual multiplication takes 17 internal clock cycles. It is expected that the chip would run at a 10 MHz internal clock frequency (external clock divided by two). This results in an actual multiplication time (16-bit x 16-bit) of 1.7  $\mu$ s. If the time to load operands and read results is included:

Number of internal clock cycles to load 5 registers: 30  
Number of internal clock cycles to read 4 registers: 24

The total internal clock cycles to perform a multiplication is 71. This results in a net multiplication time of 7.1  $\mu$ s. Note that this would be the worst case. This assumes that all of the operands are loaded from the external world as opposed to some of the operands being already in place as a result of a previous operation whose destination register is one of the math unit registers.

**Performance of division.** The actual division needs 20 internal clock cycles. This translates to 2.0  $\mu$ s for the actual division at 10 MHz (internal clock speed). If the time to load operands and read results is included:

Number of internal clock cycles to load operands: 42  
Number of internal clock cycles to read results: 24

The total internal clock cycles to perform a division is 86. This translates to 8.6  $\mu$ s at 10 MHz.

## Counter/Timers

This section describes the enhanced features of the counter/timers (CTC) on the Z86C93. It contains the register mapping of CTC registers and the bit functions of the newly added Timer2 control register.

In a standard Z8, there are two 8-bit programmable counter/timers (T0 and T1), each driven by its own 6-bit programmable prescaler. The T1 prescaler is driven by internal or external clock sources; however, the T0 prescaler is driven by the internal clock only.

The 6-bit prescalers divide the input frequency of the clock source by any integer number from 1 to 64. Each prescaler drives its counter, which decrements the value (1 to 256) that has been loaded into the counter. When the counter reaches the end of the count, a timer interrupt request IRQ4 (T0) or IRQ5 (T1), is generated.

## Interrupts

The Z86C93 has six different interrupts from nine different sources. The interrupts are maskable and prioritized. The nine sources are divided as follow: four sources are claimed by Port 3 lines P30-P33, one in Serial Out, one in Serial In, and three in the counter/timers. The Interrupt Mask Register globally or individually enables or disables the six interrupt requests. When more than one interrupt is pending, priorities are resolved by a programmable priority encoder that is controlled by the Interrupt Priority register. All Z86C93 interrupts are vectored through locations in the program memory. When an interrupt machine cycle is activated an interrupt request is granted. Thus, this disables all of the subsequent interrupts, save the Program Counter and Status Flags, and then branches to the program memory vector location reserved for that interrupt. This memory location and the next byte contain the 16-bit address of the interrupt service routine for that particular interrupt request.

To accommodate polled interrupt systems, interrupt inputs are masked and the Interrupt Request register is polled to determine which of the interrupt requests need service. Software initiated interrupts are supported by setting the appropriate bit in the Interrupt Request Register (IRQ).

Internal interrupt requests are sampled on the falling edge of the last cycle of every instruction. The interrupt request must be valid 5TpC before the falling edge of the last clock cycle of the currently executing instruction.

When the device samples a valid interrupt request, the next 48 (external) clock cycles are used to prioritize the interrupt, and push the two PC bytes and the FLAG register on the stack. The following nine cycles are used to fetch the interrupt vector from external memory. The first byte of the interrupt service routine is fetched beginning on the 58<sup>th</sup> TpC cycle following the internal sample point, which corresponds to the 63<sup>rd</sup> TpC cycle following the external interrupt sample point.

Figure 21. Interrupt Block Diagram

**Table 7. Interrupt Types, Sources, and Vectors**

Name	Source	Vector Location	Comments
IRQ 0	/DAV 0, P32, T2	0, 1	External (P32), Programmable Rise or Fall Edge Triggered
IRQ 1,	P33	2, 3	External (P33), Fall Edge Triggered
IRQ 2	/DAV 2, P31, T <sub>IN</sub>	4, 5	External (P31), Programmable Rise or Fall Edge Triggered
IRQ 3	P30, Serial In	6, 7	External (P30), Fall Edge Triggered
IRQ 4	T0, Serial Out	8, 9	Internal
IRQ 5	T1	10, 11	Internal

## Clock

The Z86C93 on-chip oscillator has a high-gain, parallel-resonant amplifier for connection to a crystal, LC, ceramic resonator, or any suitable external clock source (XTAL1=Input, XTAL2=Output). The external clock levels

are not TTL. The crystal should be AT cut, 1 MHz to 25 MHz max, and series resistance (RS) is less than or equal to 100 Ohms. The crystal should be connected across XTAL1 and XTAL2 using the recommended capacitors (10 pF < CL < 100 pF) from each pin to ground (Figure 20).
