Welcome to E-XFL.COM

Understanding Embedded - Microprocessors

Embedded microprocessors are specialized computing chips designed to perform specific tasks within an embedded system. Unlike general-purpose microprocessors found in personal computers, embedded microprocessors are tailored for dedicated functions within larger systems, offering optimized performance, efficiency, and reliability. These microprocessors are integral to the operation of countless electronic devices, providing the computational power necessary for controlling processes, handling data, and managing communications.

Applications of Embedded - Microprocessors

Embedded microprocessors are utilized across a broad spectrum of applications, making them indispensable in

Details	
Product Status	Obsolete
Core Processor	Z8L180
Number of Cores/Bus Width	1 Core, 8-Bit
Speed	20MHz
Co-Processors/DSP	-
RAM Controllers	DRAM
Graphics Acceleration	No
Display & Interface Controllers	-
Ethernet	-
SATA	-
USB	-
Voltage - I/O	3.3V
Operating Temperature	0°C ~ 70°C (TA)
Security Features	-
Package / Case	68-LCC (J-Lead)
Supplier Device Package	68-PLCC
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8l18020vsc

GENERAL DESCRIPTION (Continued)

Power connections follow the conventional descriptions below:

Connection	Circuit	Device
Power	V_{CC}	V_{DD}
Ground	GND	V_{SS}

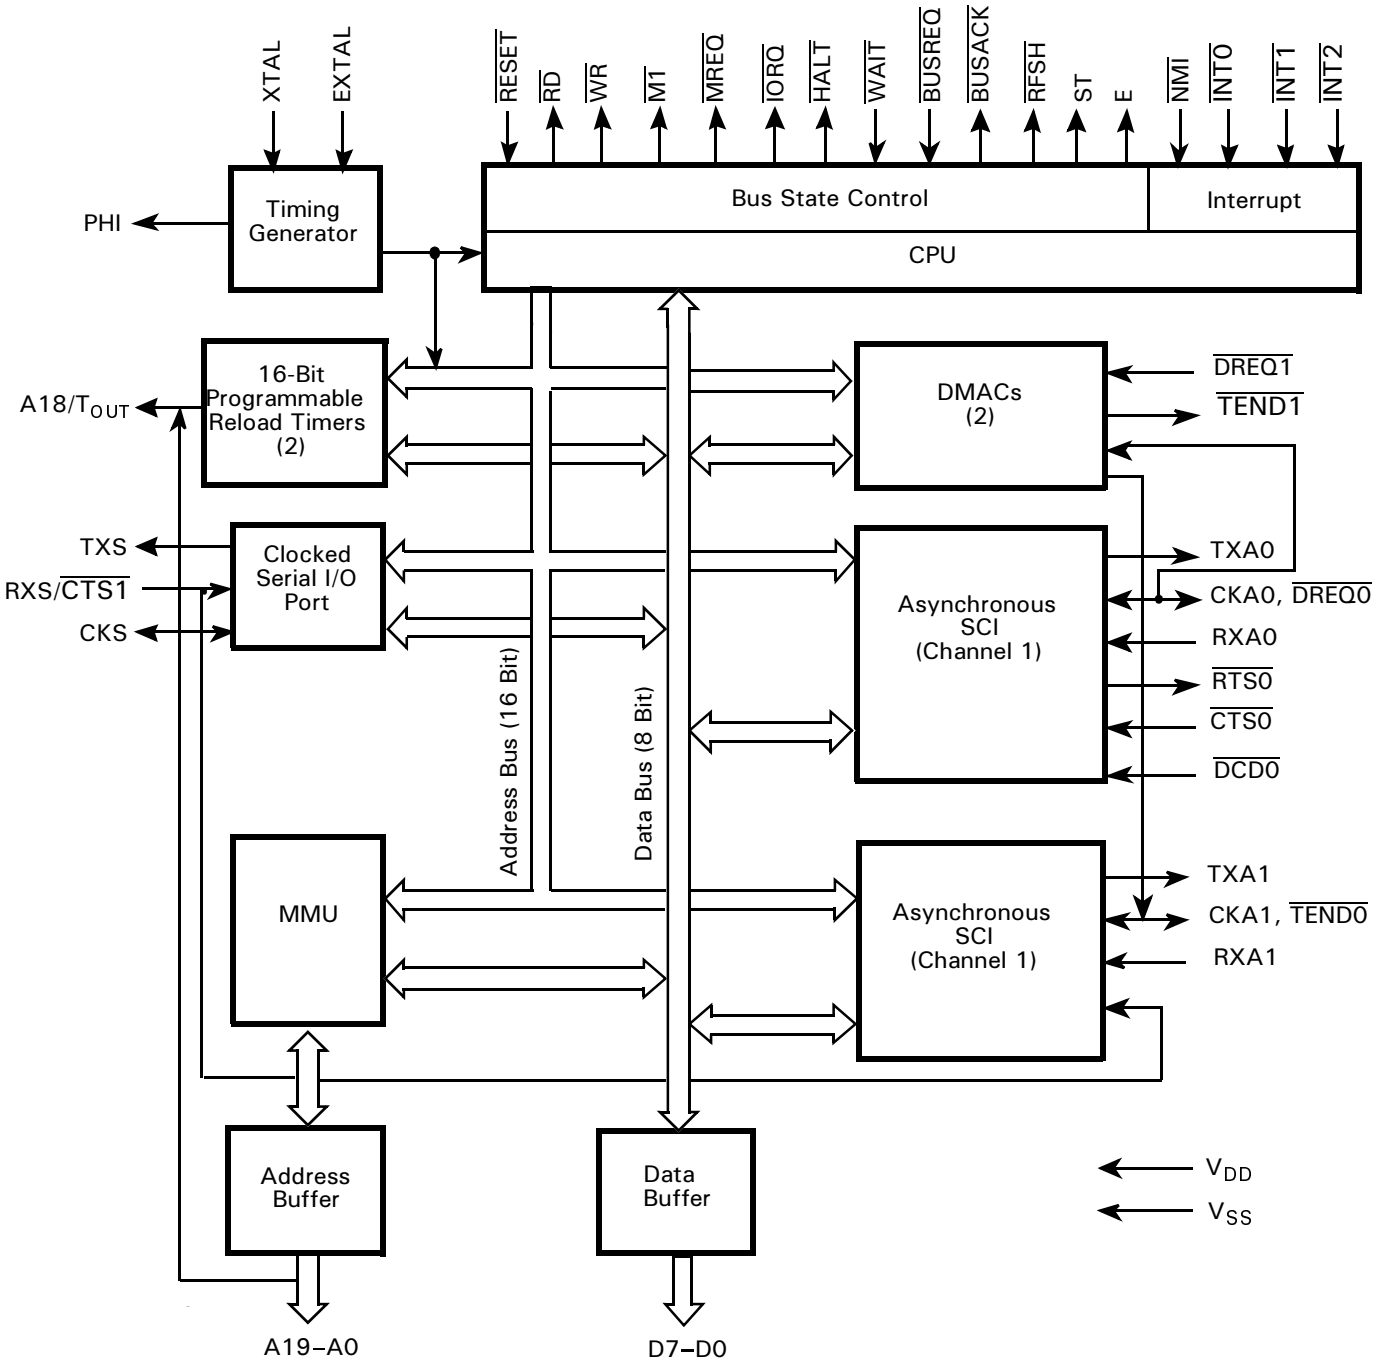

Figure 1. Z8S180/Z8L180 Functional Block Diagram

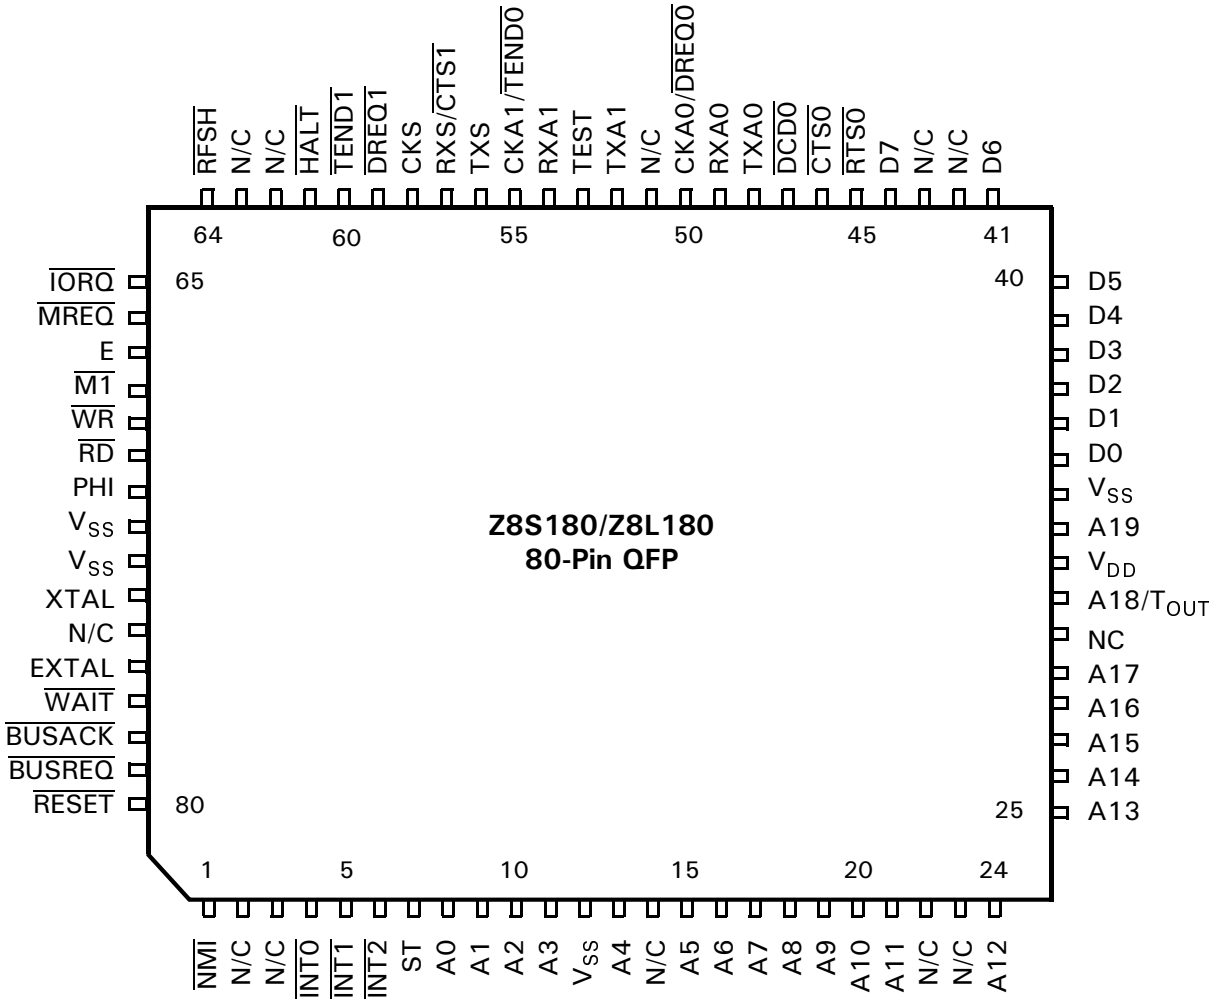

Figure 4. Z8S180/Z8L180 80-Pin QFP Pin Configuration

Table 1. Z8S180/Z8L180 Pin Identification

Pin Number and Package Type			Default	Secondary	
QFP	PLCC	DIP	Function	Function	Control
1	9	8	$\overline{NMI}$		
2			NC		
3			NC		
4	10	9	$\overline{INT0}$		
5	11	10	$\overline{INT1}$		
6	12	11	$\overline{INT2}$		
7	13	12	ST		
8	14	13	A0		
9	15	14	A1		
10	16	15	A2		
11	17	16	A3		
12	18		V_{SS}		

Table 4. Multiplexed Pin Descriptions

A18/TOUT	During RESET, this pin is initialized as A18. If either the TOC1 or the TOC0 bit of the Timer Control register (TCR) is set to 1, the T_{OUT} function is selected. If TOC1 and TOC0 are cleared to 0, the A18 function is selected.
CKA0/$\overline{\text{DREQ0}}$	During RESET, this pin is initialized as CKA0. If either DM1 or SM1 in the DMA Mode register (DMODE) is set to 1, the $\overline{\text{DREQ0}}$ function is selected.
CKA1/$\overline{\text{TEND0}}$	During RESET, this pin is initialized as CKA1. If the CKA1D bit in ASCI control register ch1 (CNTLA1) is set to 1, the $\overline{\text{TEND0}}$ function is selected. If the CKA1D bit is set to 0, the CKA1 function is selected.
RXS/$\overline{\text{CTS1}}$	During RESET, this pin is initialized as RXS. If the CTS1E bit in the ASCI status register ch1 (STAT1) is set to 1, the $\overline{\text{CTS1}}$ function is selected. If the CTS1E bit is set to 0, the RXS function is selected.

OPERATION MODES (Continued)

The Z8S180/Z8L180 leaves HALT mode in response to:

- Low on $\overline{\text{RESET}}$
- Interrupt from an enabled on-chip source
- External request on $\overline{\text{NMI}}$
- Enabled external request on $\overline{\text{INT0}}$, $\overline{\text{INT1}}$, or $\overline{\text{INT2}}$

In case of an interrupt, the return address is the instruction following the HALT instruction. The program can either branch back to the HALT instruction to wait for another interrupt or can examine the new state of the system/application and respond appropriately.

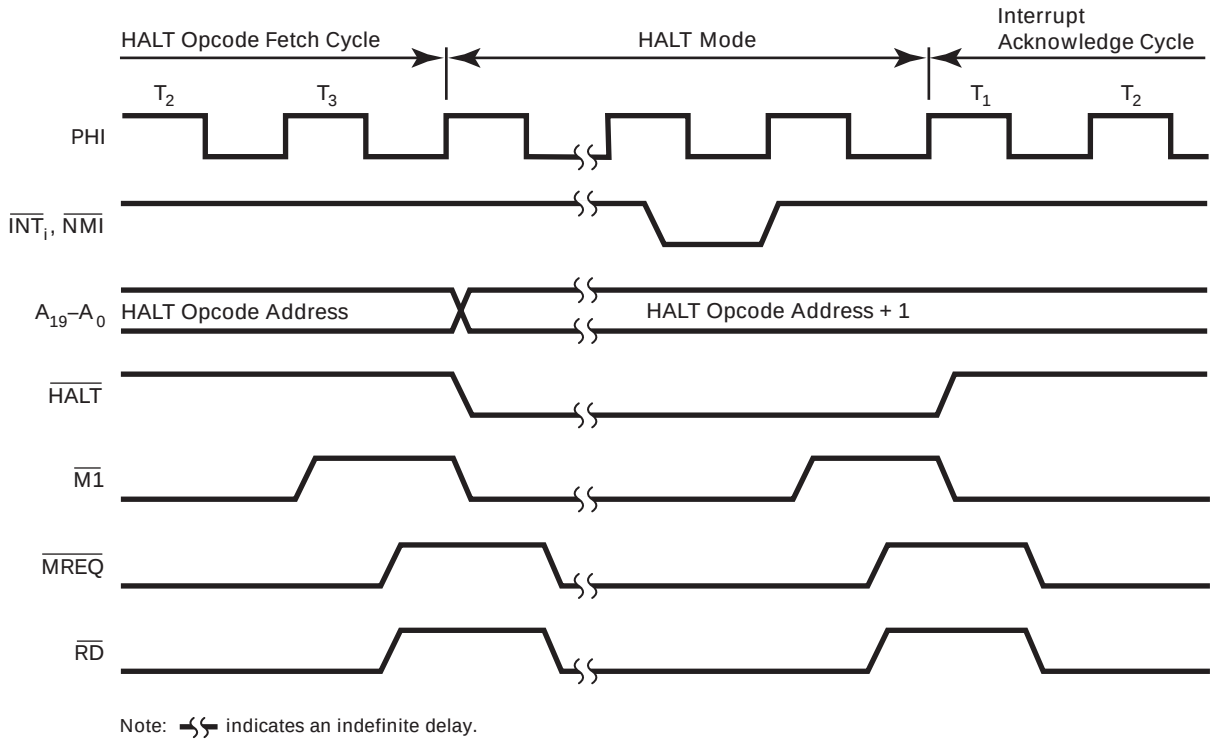

Figure 13. HALT Timing

SLEEP Mode. This mode is entered by keeping the IOSTOP bit (ICR5) and bits 3 and 6 of the CPU Control Register (CCR3, CCR6) all zero and executing the SLP instruction. The oscillator and PHI output continue operating, but are blocked from the CPU core and DMA channels to reduce power consumption. DRAM refresh stops, but interrupts and granting to an external Master can occur. Except when the bus is granted to an external Master, A19–0 and all control signals except $\overline{\text{HALT}}$ are maintained High. $\overline{\text{HALT}}$ is Low. I/O operations continue as before the SLP instruction, except for the DMA channels.

The Z8S180/Z8L180 leaves SLEEP mode in response to a Low on $\overline{\text{RESET}}$, an interrupt request from an on-chip source, an external request on $\overline{\text{NMI}}$, or an external request on $\overline{\text{INT0}}$, $\overline{\text{INT1}}$, or $\overline{\text{INT2}}$.

If an interrupt source is individually disabled, it cannot bring the Z8S180/Z8L180 out of SLEEP mode. If an interrupt source is individually enabled, and the IEF bit is 1 so that interrupts are globally enabled (by an EI instruction), the highest priority active interrupt occurs with the return address being the instruction after the SLP instruction. If an interrupt source is individually enabled, but the IEF bit is 0 so that interrupts are globally disabled (by a DI instruction), the Z8S180/Z8L180 leaves SLEEP mode by simply executing the following instruction(s).

This condition provides a technique for synchronization with high-speed external events without incurring the latency imposed by an interrupt-response sequence. Figure 14 depicts the timing for exiting SLEEP mode due to an interrupt request.

Note: The Z8S180/Z8L180 takes about 1.5 clock ticks to restart.

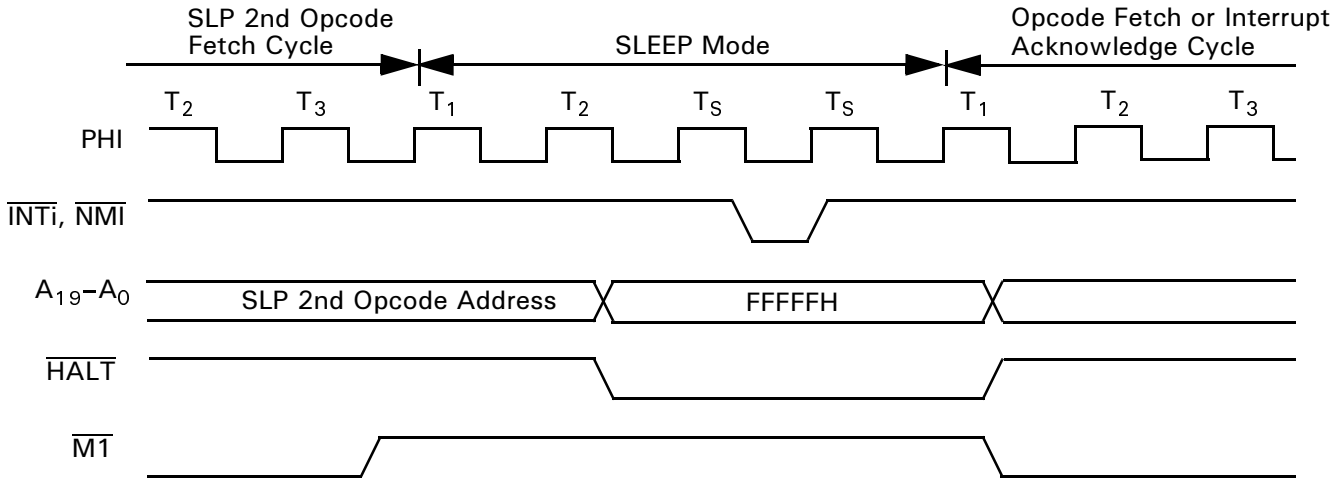

Figure 14. SLEEP Timing

IOSTOP Mode. IOSTOP mode is entered by setting the IOSTOP bit of the I/O Control Register (ICR) to 1. In this case, on-chip I/O (ASCI, CSI/O, PRT) stops operating. However, the CPU continues to operate. Recovery from IOSTOP mode is performed by resetting the IOSTOP bit in ICR to 0.

SYSTEM STOP Mode. SYSTEM STOP mode is the combination of SLEEP and IOSTOP modes. SYSTEM STOP mode is entered by setting the IOSTOP bit in ICR to 1 followed by execution of the SLP instruction. In this mode, on-chip I/O and CPU stop operating, reducing power consumption, but the PHI output continues to operate. Recovery from SYSTEM STOP mode is the same as recovery from SLEEP mode except that internal I/O sources (disabled by IOSTOP) cannot generate a recovery interrupt.

IDLE Mode. Software puts the Z8S180/Z8L180 into this mode by performing the following actions:

- Set the IOSTOP bit (ICR5) to 1
- Set CCR6 to 0
- Set CCR3 to 1
- Execute the SLP instruction

The oscillator keeps operating but its output is blocked to all circuitry including the PHI pin. DRAM refresh and all internal devices stop, but external interrupts can occur. Bus granting to external Masters can occur if the BREST bit in the CPU control Register (CCR5) was set to 1 before IDLE mode was entered.

The Z8S180/Z8L180 leaves IDLE mode in response to a Low on $\overline{\text{RESET}}$, an external interrupt request on $\overline{\text{NMI}}$, or an external interrupt request on $\overline{\text{INT0}}$, $\overline{\text{INT1}}$ or $\overline{\text{INT2}}$ that is enabled in the INT/TRAP Control Register. As previously described for SLEEP mode, when the Z8S180/Z8L180 leaves IDLE mode due to an $\overline{\text{NMI}}$, or due to an enabled external interrupt request when the $\overline{\text{IEF}}$ flag is 1 due to an EI instruction, the device starts by performing the interrupt with the return address of the instruction after the SLP instruction.

If an external interrupt enables the INT/TRAP control register while the IEF1 bit is 0, Z8S180/Z8L180 leaves IDLE mode; specifically, the processor restarts by executing the instructions following the SLP instruction.

Figure 15 indicates the timing for exiting IDLE mode due to an interrupt request.

Note: The Z8S180/Z8L180 takes about 9.5 clocks to restart.

OPERATION MODES (Continued)

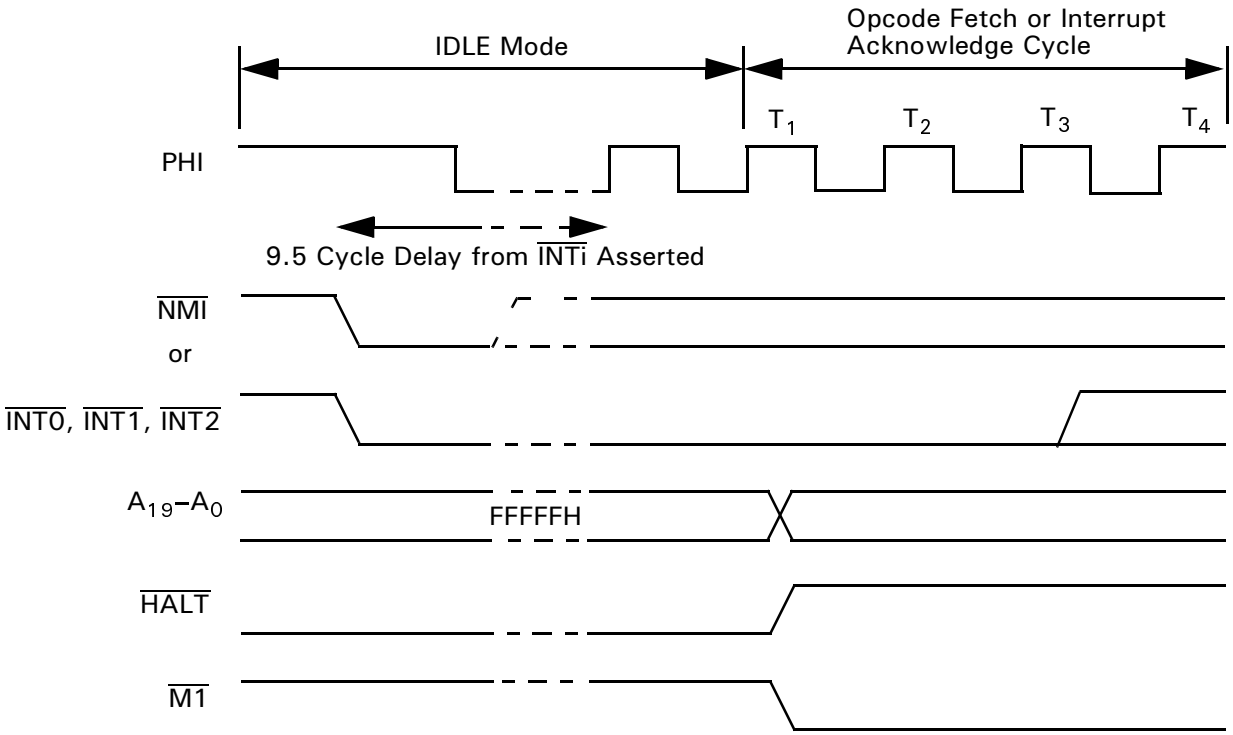

Figure 15. Z8S180/Z8L180 IDLE Mode Exit Due To External Interrupt

While the Z8S180/Z8L180 is in IDLE mode, it grants the bus to an external Master if the BREXT bit (CCR5) is 1. Figure 16 depicts the timing for this sequence.

Note: A response to a bus request takes 8 clock cycles longer than in normal operation.

After the external Master negates the Bus Request, the Z8S180/Z8L180 disables the PHI clock and remains in IDLE mode.

DC CHARACTERISTICS—Z8S180

Table 6. Z8S180 DC Characteristics
V_{DD} = 5V ±10%; V_{SS} = 0V

Symbol	Item	Condition	Min	Typ	Max	Unit
V_{IH1}	Input H Voltage $\overline{RESET}$, EXTAL, $\overline{NMI}$		V_{DD} –0.6	—	V_{DD} +0.3	V
V_{IH2}	Input H Voltage Except $\overline{RESET}$, EXTAL, $\overline{NMI}$		2.0	—	V_{DD} +0.3	V
V_{IH3}	Input H Voltage CKS, CKA0, CKA1		2.4	—	V_{DD} +0.3	V

TIMING DIAGRAMS (Continued)

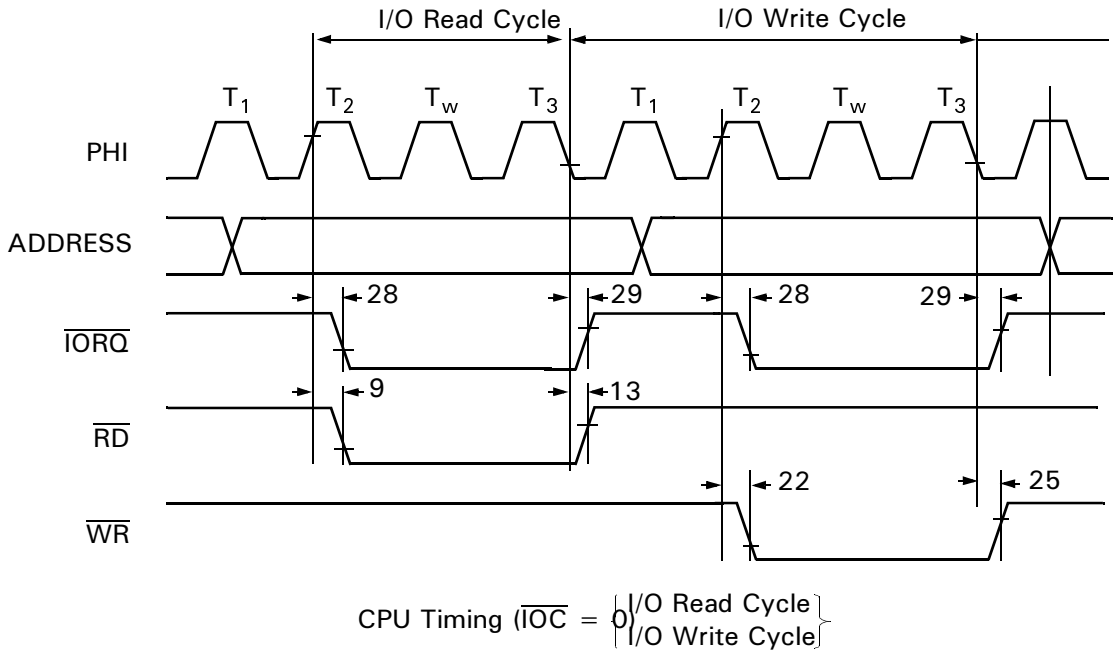

Figure 22. CPU Timing ($\overline{IOC}$ = 0) (I/O Read Cycle, I/O Write Cycle)

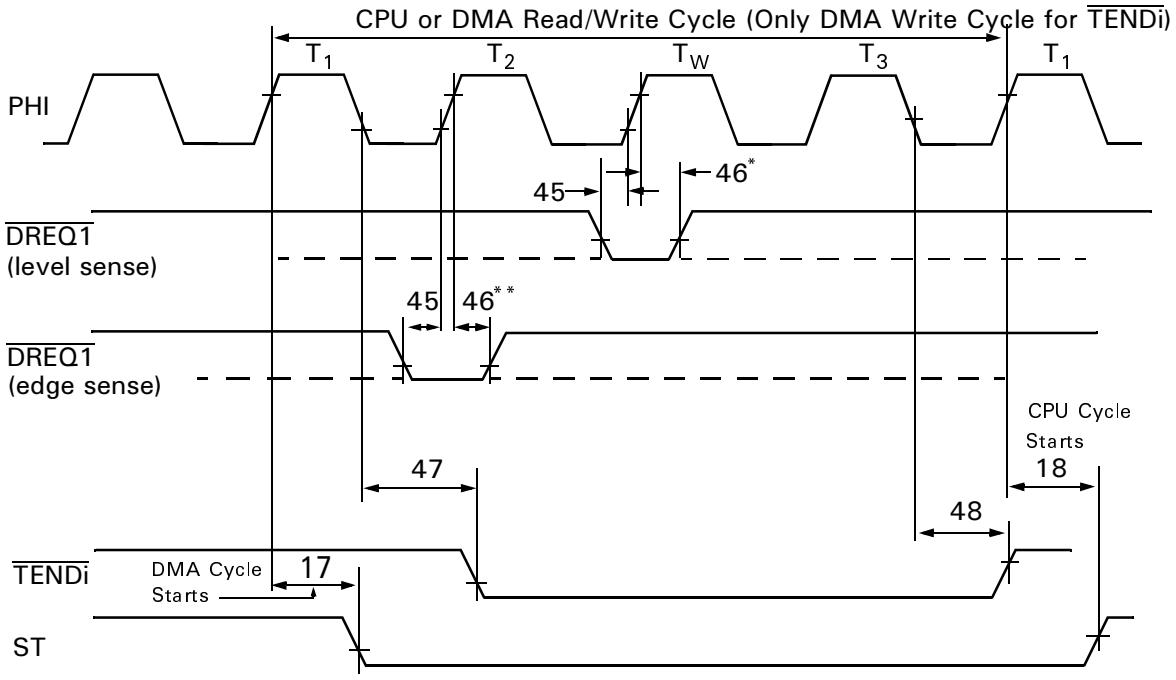

Notes:

*T_{DRQS} and T_{DRQH} are specified for the rising edge of the clock followed by T_3.

**T_{DRQS} and T_{DRQH} are specified for the rising edge of the clock.

Figure 23. DMA Control Signals

ASCI0 requests an interrupt when $\overline{DCD0}$ goes High. RIE is cleared to 0 by RESET.

$\overline{DCD0}$: Data Carrier Detect (Bit 2 STAT0). This bit is set to 1 when the pin is High. It is cleared to 0 on the first READ of STAT0 following the pin's transition from High to Low and during RESET. When bit 6 of the ASEXT0 register is 0 to select auto-enabling, and the pin is negated (High), the receiver is reset and its operation is inhibited.

$\overline{CTS1E}$: Clear To Send (Bit 2 STAT1). Channel 1 features an external $\overline{CTS1}$ input, which is multiplexed with the receive data pin RSX for the CSI/O. Setting this bit to 1 selects the CTS1 function; clearing the bit to 0 selects the RXS function.

TDRE: Transmit Data Register Empty (Bit 1). TDRE = 1 indicates that the TDR is empty and the next transmit data byte is written to TDR. After the byte is written to TDR, TDRE is cleared to 0 until the ASCI transfers the byte from TDR to the TSR and then TDRE is again set to 1. TDRE is set to 1 in IOSTOP mode and during RESET. On ASCI0, if the $\overline{CTS0}$ pin is auto-enabled in the ASEXT0 register and the pin is High, TDRE is reset to 0.

TIE: Transmit Interrupt Enable (Bit 0). TIE should be set to 1 to enable ASCI transmit interrupt requests. If TIE = 1, an interrupt is requested when TDRE = 1. TIE is cleared to 0 during RESET.

ASCI TRANSMIT DATA REGISTERS

Register addresses 06H and 07H hold the ASCI transmit data for channel 0 and channel 1, respectively.

ASCI Transmit Data Registers Channel 0

Mnemonic TDR0
Address 06H

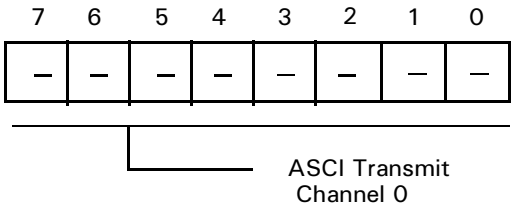

Figure 36. ASCI Register

ASCI Transmit Data Registers Channel 1

Mnemonic TDR1
Address 07H

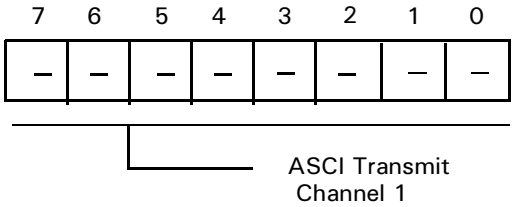

Figure 37. ASCI Register

never both set to 1 at the same time. TE is cleared to 0 during RESET and IOSTOP mode.

SS2, 1, 0: Speed Select 2, 1, 0 (Bits 2–0). SS2, SS1 and SS0 select the CSI/O transmit/receive clock source and speed. SS2, SS1 and SS0 are all set to 1 during $\overline{\text{RESET}}$. Table 11 indicates CSI/O Baud Rate Selection.

Table 11. CSI/O Baud Rate Selection

SS2	SS1	SS0	Divide Ratio
0	0	0	÷20
0	0	1	÷40
0	1	0	÷80
0	1	1	÷160
1	0	0	÷320
1	0	1	÷640
1	1	0	÷1280
1	1	1	External Clock Input (Less Than ÷20)

After $\overline{\text{RESET}}$, the CKS pin is configured as an external clock input (SS2, SS1, SS0 = 1). Changing these values causes CKS to become an output pin and the selected clock is output when transmit or receive operations are enabled.

ASCI EXTENSION CONTROL REGISTER CHANNEL 0 AND CHANNEL 1

The ASCI Extension Control Registers (ASEXT0 and ASEXT1) control functions that have been added to the ASCIs in the Z8S180/Z8L180 family. All bits in this register reset to 0.

ASCI Extension Control Register 0 (ASEXT0 I/O Address = 12H)

Bit	7	6	5	4	3	2	1	0
	Reserved	DCD0 Disable	CTS0 Disable	X1	BRG0 Mode	Break Enable	Break	Send Break

ASCI Extension Control Register 1 (ASEXT1 I/O Address = 13H)

Bit	7	6	5	4	3	2	1	0
	Reserved	Reserved	Reserved	X1	BRG1 Mode	Break Enable	Break	Send Break

Figure 47. ASCI Extension Control Registers, Channels 0 and 1

DCD0 Disable (Bit 6, ASCI0 Only). If this bit is 0, then the $\overline{\text{DCD0}}$ pin auto-enables the ASCI0 receiver, such that when the pin is negated/High, the Receiver is held in a RESET state. If this bit is 1, the state of the $\overline{\text{DCD}}$-pin has no effect on receiver operation. In either state of this bit, software can read the state of the $\overline{\text{DCD0}}$ pin in the STAT0 register, and the receiver interrupts on a rising edge of $\overline{\text{DCD0}}$.

CTS0 Disable (Bit 5, ASCI0 Only). If this bit is 0, then the $\overline{\text{CTS0}}$ pin auto-enables the ASCIO transmitter, in that when the pin is negated/High, the TDRE bit in the STAT0 register is forced to 0. If this bit is 1, the state of the $\overline{\text{CTS0}}$ pin has no effect on the transmitter. Regardless of the state of this bit, software can read the state of the $\overline{\text{CTS0}}$ pin the CNTLB0 register.

X1 (Bit 4). If this bit is 1, the clock from the Baud Rate Generator or CKA pin is taken as a 1X-bit clock (sometimes called *isochronous mode*). In this mode, receive data on the RXA pin must be synchronized to the clock on the CKA pin, regardless of whether CKA is an input or an output. If this bit is 0, the clock from the Baud Rate Generator or CKA pin is divided by 16 or 64 per the DR bit in the CNTLB register, to obtain the actual bit rate. In this mode, receive data on the RXA pin is not required to be synchronized to a clock.

BRG Mode (Bit 3). If the SS2–0 bits in the CNTLB register are not 111, and this bit is 0, the ASCI Baud Rate Generator divides PHI by 10 or 30, depending on the PS bit in CNTLB, and factored by a power of two (selected by the SS2–0 bits), to obtain the clock that is presented to the transmitter and receiver and output on the CKA pin. If SS2–0 are not 111, and this bit is 1, the Baud Rate Generator divides PHI by twice the sum of the 16-bit value (programmed into the Time Constant registers) and 2. This mode is identical to the operation of the baud rate generator in the ESCC.

Break Enable (Bit 2). If this bit is 1, the receiver detects BREAK conditions and report them in bit 1, and the transmitter sends BREAKs under the control of bit 0.

Break Detect (Bit 1). The receiver sets this read-only bit to 1 when an all-zero character with a Framing Error becomes the oldest character in the Rx FIFO. The bit is cleared when software writes a 0 to the EFR bit in CNTLA register, also by RESET, by IOSTOP mode, and for ASCI0, if the $\overline{\text{DCD0}}$ pin is auto-enabled and is negated (High).

Send Break (Bit 0). If this bit and bit 2 are both 1, the transmitter holds the TXA pin Low to send a BREAK condition. The duration of the BREAK is under software control (one of the PRTs or CTCs can be used to time it). This bit resets to 0, in which state TXA carries the serial output of the transmitter.

DMA BYTE COUNT REGISTER CHANNEL 0

The DMA Byte Count Register Channel 0 specifies the number of bytes to be transferred. This register contains 16 bits and may specify up to 64-KB transfers. When one byte is transferred, the register is decremented by one. If n bytes should be transferred, n must be stored before the DMA operation.

Note: All DMA Count Register channels are undefined during RESET.

DMA I/O ADDRESS REGISTER

The DMA I/O Address Register specifies the I/O device for channel 1 transfers. This address may be a destination or source I/O device. IAR1L and IAR1H each contain 8 address bits. The most significant byte identifies the Request Handshake signal and controls the Alternating Channel feature.

DMA I/O Address Register Channel 1 Low

Mnemonic IAR1L
Address 2BH

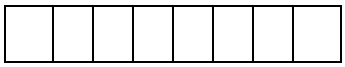

Figure 68. DMA I/O Address Register Channel 1 Low

DMA I/O Address Register Channel 1 High

Mnemonic IAR1H
Address 2CH

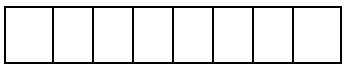

Figure 69. DMA I/O Address Register Channel 1 High

DMA I/O Address Register Channel 1 B

Mnemonic IAR1B
Address 2DH

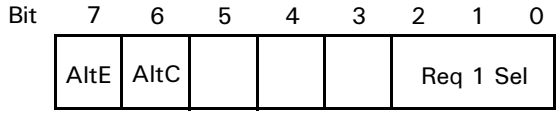

Figure 70. DMA I/O Address Register Channel 1 B

AltE. The AltE bit should be set only when both DMA channels are programmed for the same I/O source or I/O destination. In this case, a *channel end* condition (byte count = 0) on channel 0 sets bit 6 (AltC), which subsequently enables the channel 1 request and blocks the channel 0 request. Similarly, a channel end condition on channel 1 clears bit 6 (AltC), which then enables the channel 0 request and blocks the channel 1 request. For external requests, the request from the device must be routed or connected to both the DREQ0 and DREQ1 pins.

AltC. If bit (AltE) is 0, the AltC bit has no effect. When bit 7 (AltE) is 1 and the AltC bit is 0, the request signal selected by bits 2–0 is not presented to channel 1; however, the channel 0 request operates normally. When AltE is 1 and AltC is 1, the request selected by SAR18–16 or DAR18–16 is not presented to channel 0; however, the channel 1 request operates normally. The AltC bit can be written by software to select which channel should operate first; however, this operation should be executed only when both channels are stopped (both DE1 and DE0 are 0).

Req1Sel. If bit DIM1 in the DCNTL register is 1, indicating an I/O source, the following bits select which source handshake signal should control the transfer:

000	DREQ1 pin
001	ASCI0 RDRF
010	ASCI1 RDRF
Other	Reserved, do not program

If DIM1 is 0, indicating an I/O destination, the following bits select which destination handshake signal should control the transfer:

000	DREQ1 pin
001	ASCI0 TDRE
010	ASCI1 TDRE
Other	Reserved, do not program

DMA STATUS REGISTER

The DMA Status Register (DSTAT) is used to enable and disable DMA transfer and DMA termination interrupts. DSTAT also indicates DMA transfer status, Completed or In Progress.

DMA Status Register

Mnemonic DSTAT
Address 30H

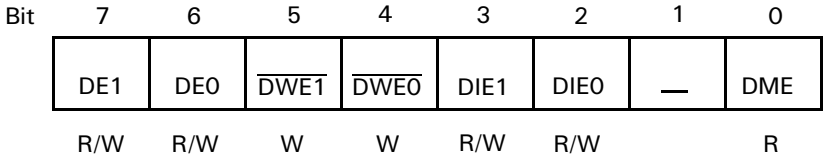

Figure 71. DMA Status Register (DSTAT: I/O Address = 30H)

DE1: DMA Enable Channel 1 (Bit 7). When DE1 = 1 and DME = 1, channel 1 DMA is enabled. When a DMA transfer terminates (BCR1 = 0), DE1 is reset to 0 by the DMAC. When DE1 = 0 and the DMA interrupt is enabled (DIE1 = 1), a DMA interrupt request is made to the CPU.

To perform a software WRITE to DE1, $\overline{\text{DWE1}}$ should be written with a 0 during the same register WRITE access. Writing DE1 to 0 disables channel 1 DMA, but DMA is restartable. Writing DE1 to 1 enables channel 1 DMA and automatically sets DMA Main Enable (DME) to 1. DE1 is cleared to 0 during RESET.

DE0: DMA Enable Channel 0 (Bit 6). When DE0 = 1 and DME = 1, channel 0 DMA is enabled. When a DMA transfer terminates (BCR0 = 0), DE0 is reset to 0 by the DMAC. When DE0 = 0 and the DMA interrupt is enabled (DIE0 = 1), a DMA interrupt request is made to the CPU.

To perform a software WRITE to DE0, $\overline{\text{DWE0}}$ should be written with 0 during the same register WRITE access. Writing DE0 to 0 disables channel 0 DMA. Writing DE0 to 1 enables channel 0 DMA and automatically sets DMA Main Enable (DME) to 1. DE0 is cleared to 0 during RESET.

$\overline{\text{DWE1}}$: DE1 Bit Write Enable (Bit 5). When performing any software WRITE to DE1, this bit should be written with 0 during the same access. $\overline{\text{DWE1}}$ always reads as 1.

$\overline{\text{DWE0}}$: DE0 Bit Write Enable (Bit 4). When performing any software WRITE to DE0, this bit should be written with 0 during the same access. $\overline{\text{DWE0}}$ always reads as 1.

DIE1: DMA Interrupt Enable Channel 1 (Bit 3). When DIE0 is set to 1, the termination channel 1 DMA transfer (indicated when DE1 = 0) causes a CPU interrupt request to be generated. When DIE0 = 0, the channel 0 DMA termination interrupt is disabled. DIE0 is cleared to 0 during RESET.

DIE0: DMA Interrupt Enable Channel 0 (Bit 2). When DIE0 is set to 1, the termination channel 0 of DMA transfer (indicated when DE0 = 0) causes a CPU interrupt request to be generated. When DIE0 = 0, the channel 0 DMA termination interrupt is disabled. DIE0 is cleared to 0 during RESET.

DME: DMA Main Enable (Bit 0). A DMA operation is only enabled when its DE bit (DE0 for channel 0, DE1 for channel 1) and the DME bit is set to 1.

When $\overline{\text{NMI}}$ occurs, DME is reset to 0, thus disabling DMA activity during the $\overline{\text{NMI}}$ interrupt service routine. To restart DMA, DE– and/or DE1 should be written with a 1 (even if the contents are already 1). This condition automatically sets DME to 1, allowing DMA operations to continue.

Note: DME cannot be directly written. The bit is cleared to 0 by $\overline{\text{NMI}}$ or indirectly set to 1 by setting DE0 and/or DE1 to 1. DME is cleared to 0 during RESET.

INTERRUPT VECTOR LOW REGISTER

Bits 7–5 of the Interrupt Vector Low Register (I_L) are used as bits 7–5 of the synthesized interrupt vector during interrupts for the $\overline{INT1}$ and $\overline{INT2}$ pins and for the DMAs, ASCIs, PRTs, and CSI/O. These three bits are cleared to 0 during RESET (Figure 74).

Interrupt Vector Low Register

Mnemonic: IL
Address 33H

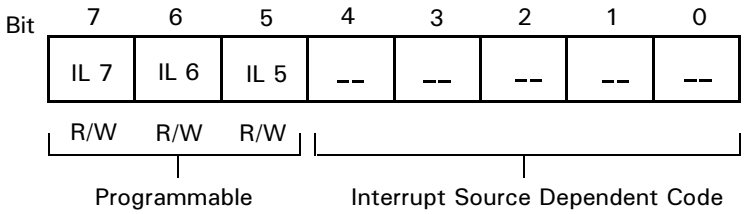

Figure 74. Interrupt Vector Low Register (IL: I/O Address = 33H)

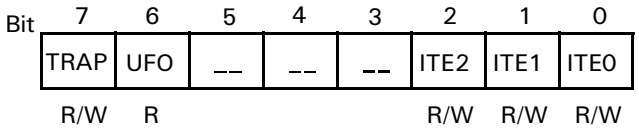
INT/TRAP CONTROL REGISTER

This register is used in handling TRAP interrupts and to enable or disable Maskable Interrupt Level 0 and the $\overline{INT1}$ and $\overline{INT2}$ pins.

INT/TRAP Control Register

Mnemonics ITC
Address 34H



TRAP (Bit 7). This bit is set to 1 when an undefined opcode is fetched. TRAP can be reset under program control by writing it with a 0; however, TRAP cannot be written with 1 under program control. TRAP is reset to 0 during RESET.

UFO: Undefined Fetch Object (Bit 6). When a TRAP interrupt occurs, the contents of UFO allow the starting address of the undefined instruction to be determined. This interrupt is necessary because the TRAP may occur on either the second or third byte of the opcode. UFO allows the stacked PC value to be correctly adjusted. If UFO = 0, the first opcode should be interpreted as the stacked PC-1. If UFO = 1, the first opcode address is stacked PC-2. UFO is Read-Only.

ITE2, 1, 0: Interrupt Enable 2, 1, 0 (Bits 2–0). ITE2 and ITE1 enable and disable the external interrupt inputs $\overline{INT2}$ and $\overline{INT1}$, respectively. ITE0 enables and disables interrupts from:

- ESCC
- Bidirectional Centronics controller
- CTCs
- External interrupt input $\overline{INT0}$

A 1 in a bit enables the corresponding interrupt level while a 0 disables it. A RESET sets ITE0 to 1 and clears ITE1 and ITE2 to 0.

TRAP Interrupt. The Z8S180/Z8L180 generates a TRAP sequence when an undefined opcode fetch occurs. This feature can be used to increase software reliability, implement an *extended* instruction set, or both. TRAP may occur during opcode fetch cycles and also if an undefined opcode is fetched during the interrupt acknowledge cycle for $\overline{INT0}$ when Mode 0 is used.

When a TRAP sequence occurs, the Z8S180/Z8L180:

1. Sets the TRAP bit in the Interrupt TRAP/Control (ITC) register to 1.
2. Saves the current Program Counter (PC) value, reflecting the location of the undefined opcode, on the stack.
3. Resumes execution at logical address 0.

Note: If logical address 0000H is mapped to physical address 00000H, the vector is the same as for RESET. In this case, testing the TRAP bit in ITC reveals whether the restart at physical address 00000H was caused by RESET or TRAP.

MMU COMMON BASE REGISTER

The Common Base Register (CBR) specifies the base address (on 4-KB boundaries) used to generate a 20-bit physical address for Common Area 1 accesses. All bits of CBR are reset to 0 during RESET.

MMU Common Base Register

Mnemonic CBR
Address 38H

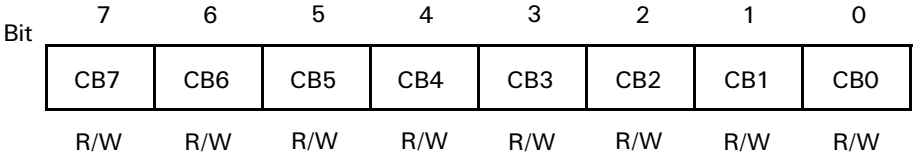


Figure 78. MMU Common Base Register (CBR: I/O Address = 38H)

MMU BANK BASE REGISTER

The Bank Base Register (BBR) specifies the base address (on 4-KB boundaries) used to generate a 20-bit physical address for Bank Area accesses. All bits of BBR are reset to 0 during RESET.

MMU Bank Base Register

Mnemonic BBR
Address 39H

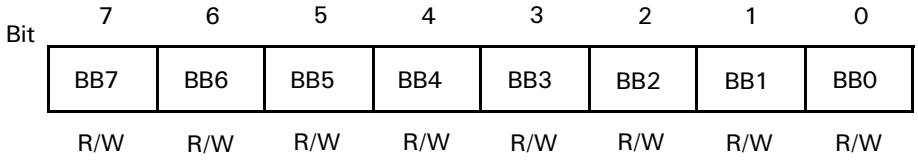

Figure 79. MMU Bank Base Register (BBR: I/O Address = 39H)

MMU COMMON/BANK AREA REGISTER

The Common/Bank Area Register (CBAR) specifies boundaries within the Z8S180/Z8L180 64-KB logical address space for up to three areas; Common Area), Bank Area and Common Area 1.

MMU Common/Bank Area Register

Mnemonic CBAR
Address 3AH
