Welcome to E-XFL.COM

Understanding Embedded - Microprocessors

Embedded microprocessors are specialized computing chips designed to perform specific tasks within an embedded system. Unlike general-purpose microprocessors found in personal computers, embedded microprocessors are tailored for dedicated functions within larger systems, offering optimized performance, efficiency, and reliability. These microprocessors are integral to the operation of countless electronic devices, providing the computational power necessary for controlling processes, handling data, and managing communications.

Applications of Embedded - Microprocessors

Embedded microprocessors are utilized across a broad spectrum of applications, making them indispensable in

Details	
Product Status	Obsolete
Core Processor	Z8S180
Number of Cores/Bus Width	1 Core, 8-Bit
Speed	33MHz
Co-Processors/DSP	-
RAM Controllers	DRAM
Graphics Acceleration	No
Display & Interface Controllers	-
Ethernet	-
SATA	-
USB	-
Voltage - I/O	5.0V
Operating Temperature	-40°C ~ 100°C (TA)
Security Features	-
Package / Case	80-BQFP
Supplier Device Package	80-QFP
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8s18033fec

GENERAL DESCRIPTION (Continued)

Power connections follow the conventional descriptions below:

Connection	Circuit	Device
Power	V_{CC}	V_{DD}
Ground	GND	V_{SS}

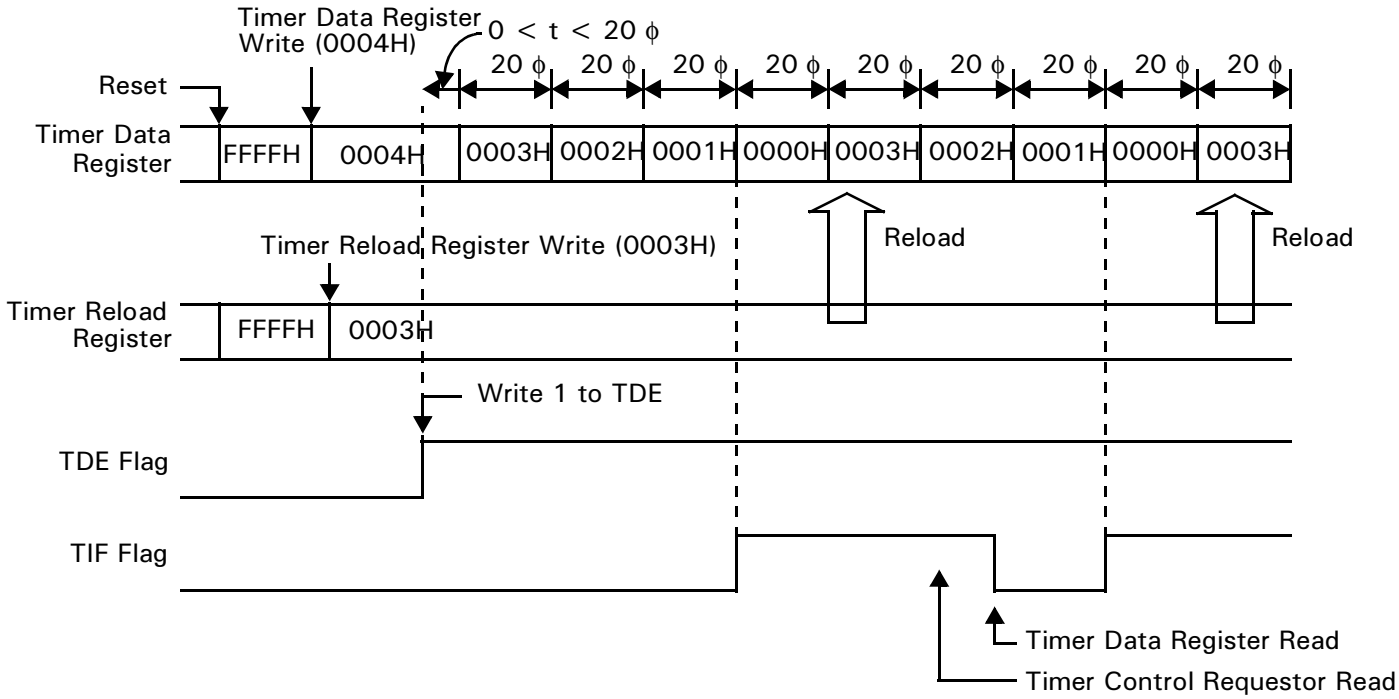

Figure 5. Timer Initialization, Count Down, and Reload Timing

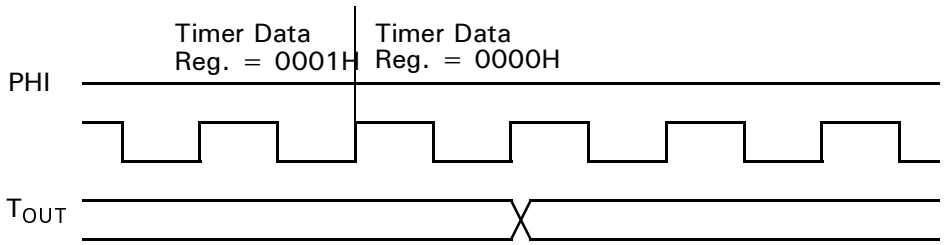

Figure 6. Timer Output Timing

Clocked Serial I/O (CSI/O). The CSI/O channel provides a half-duplex serial transmitter and receiver. This channel can be used for simple high-speed data connection to another microprocessor or microcomputer. TRDR is used for both CSI/O transmission and reception. Thus, the system design must ensure that the constraints of half-duplex operation are met (Transmit and Receive operation cannot occur simultaneously). For example, if a CSI/O transmission is attempted while the CSI/O is receiving data, a CSI/O does not work.

Note: TRDR is not buffered. Performing a CSI/O transmit while the previous transmission is still in progress causes the data to be immediately updated and corrupts the transmit operation. Similarly, reading TRDR while a transmit or receive is in progress should be avoided.

OPERATION MODES

Z80 versus 64180 Compatibility. The Z8S180/Z8L180 is descended from two different "ancestor" processors, ZiLOG's original Z80 and the Hitachi 64180. The Operating Mode Control Register (OMCR), illustrated in Figure 8, can be programmed to select between certain Z80 and 64180 differences.

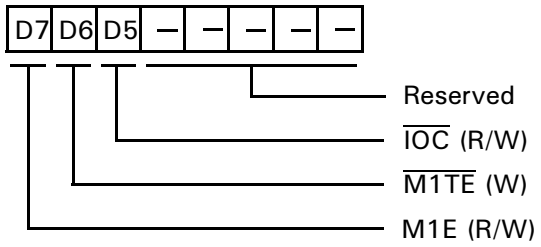

Figure 8. Operating Control Register (OMCR: I/O Address = 3EH)

M1E ($\overline{M1}$ Enable). This bit controls the $\overline{M1}$ output and is set to a 1 during RESET.

When M1E = 1, the $\overline{M1}$ output is asserted Low during opcode fetch cycles, Interrupt Acknowledge cycles, and the first machine cycle of an $\overline{NMI}$ acknowledge.

On the Z8S180/Z8L180, this choice makes the processor fetch a RETI instruction one time. When fetching a RETI from a zero-wait-state memory location, the processor uses three clock bus cycles. These bus cycles are not fully Z80-timing compatible.

When M1E = 0, the processor does not drive $\overline{M1}$ Low during the instruction fetch cycles. After fetching a RETI instruction with normal timing, the processor goes back and refetches the instruction using fully Z80-compatible cycles that include driving $\overline{M1}$ Low. This option may be required by some external Z80 peripherals to properly decode the RETI instruction. Figure 9 and Table 5 show the RETI sequence when M1E is 0.

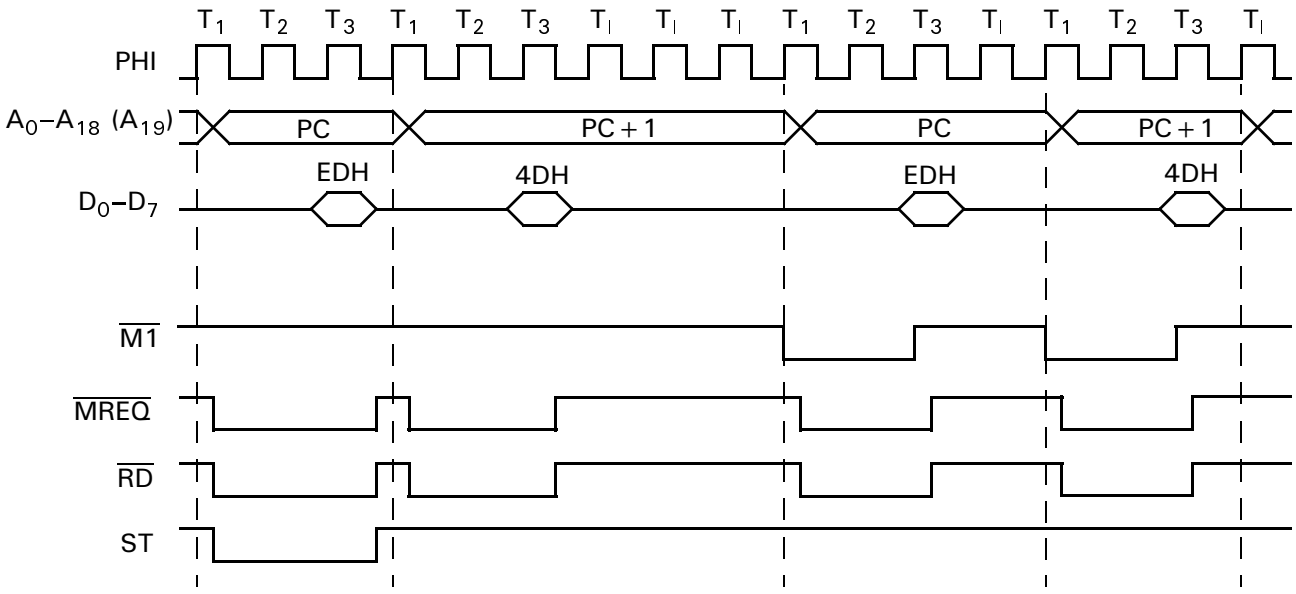

Figure 9. RETI Instruction Sequence with M1E = 0

OPERATION MODES (Continued)

Table 5. RETI Control Signal States

Machine Cycle	States	Address	Data	$\overline{RD}$	$\overline{WR}$	$\overline{MREQ}$	$\overline{IORQ}$	$\overline{M1}$ M1E = 1	$\overline{M1}$ M1E = 0	$\overline{HALT}$	ST

	Ti	NA	3-state	1	1	1	1	1	1	1	1
	Ti	NA	3-state	1	1	1	1	1	1	1	1
3	T1–T3	1st Opcode	EDH	0	1	0	1	0	0	1	1
	Ti	NA	3-state	1	1	1	1	1	1	1	1
4	T1–T3	2nd Opcode	4DH	0	1	0	1	0	1	1	1
5	T1–T3	SP	Data	0	1	0	1	1	1	1	1
6	T1–T3	SP + 1	Data	0	1	0	1	1	1	1	1

$\overline{M1TE}$ ($\overline{M1}$ Temporary Enable). This bit controls the temporary assertion of the $\overline{M1}$ signal. It is always read back as a 1 and is set to 1 during RESET.

When M1E is set to 0 to accommodate certain external Z80 peripheral(s), those same device(s) may require a pulse on $\overline{M1}$ after programming certain of their registers to complete the function being programmed.

For example, when a control word is written to the Z80 PIO to enable interrupts, no enable actually takes place until the PIO sees an active $\overline{M1}$ signal. When $\overline{M1TE}$ = 1, there is no change in the operation of the $\overline{M1}$ signal, and M1E controls its function. When $\overline{M1TE}$ = 0, the $\overline{M1}$ output is asserted during the next opcode fetch cycle regardless of the state programmed into the M1E bit. This condition is only momentary (one time) and it is not necessary to preprogram a 1 to disable the function (see Figure 10).

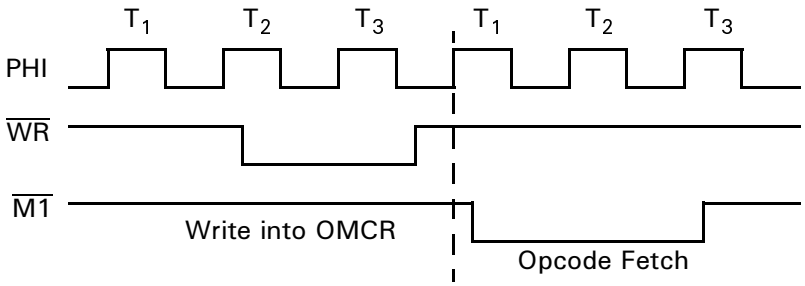

Figure 10. M1 Temporary Enable Timing

IOC (I/O Compatibility). This bit controls the timing of the $\overline{IORQ}$ and $\overline{RD}$ signals. The bit is set to 1 by RESET.

When $\overline{IOC}$ = 1, the $\overline{IORQ}$ and $\overline{RD}$ signals function the same as the Z64180 (Figure 11).

OPERATION MODES (Continued)

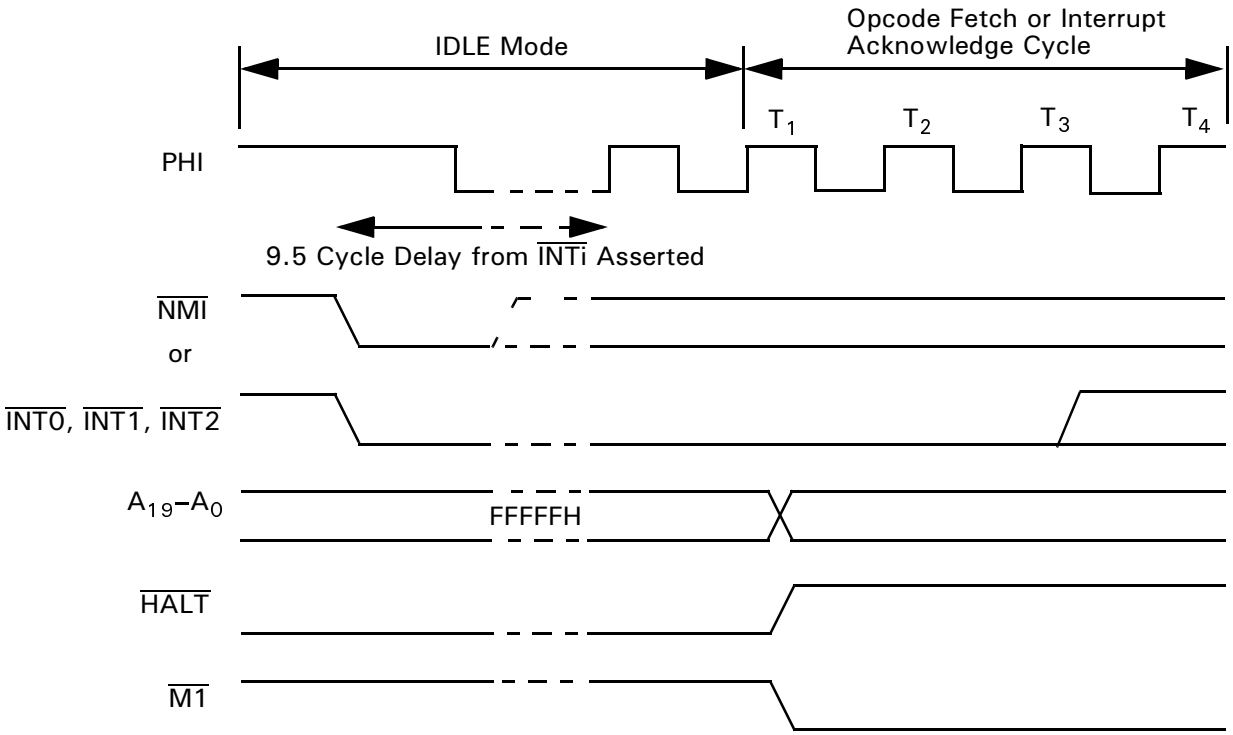

Figure 15. Z8S180/Z8L180 IDLE Mode Exit Due To External Interrupt

While the Z8S180/Z8L180 is in IDLE mode, it grants the bus to an external Master if the BREXT bit (CCR5) is 1. Figure 16 depicts the timing for this sequence.

Note: A response to a bus request takes 8 clock cycles longer than in normal operation.

After the external Master negates the Bus Request, the Z8S180/Z8L180 disables the PHI clock and remains in IDLE mode.

STANDARD TEST CONDITIONS

The following standard test conditions apply to DC Characteristics, unless otherwise noted. All voltages are referenced to V_{SS} (0V). Positive current flows into the referenced pin.

All AC parameters assume a load capacitance of 100 pF. Add a 10-ns delay for each 50-pF increase in load up to a maximum of 200 pF for the data bus and 100 pF for the address and control lines. AC timing measurements are referenced to V_{OL} MAX or V_{OL} MIN as indicated in Figures 20 through 30 (except for CLOCK, which is referenced to the 10% and 90% points). Ordering Information lists temperature ranges and product numbers. Find package drawings in Package Information.

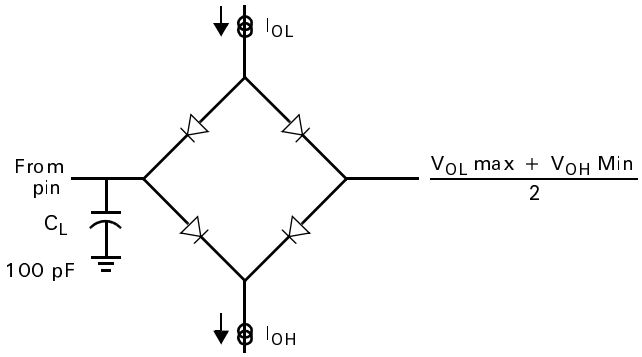

Figure 19. AC Parameter Test Circuit

ABSOLUTE MAXIMUM RATINGS

Item	Symbol	Value	Unit
Supply Voltage	V_{DD}	–0.3 ~ +7.0	V
Input Voltage	V_{IN}	–0.3 ~ V_{cc} +0.3	V
Operating Temperature	T_{OPR}	0 ~ 70	°C
Extended Temperature	T_{EXT}	–40 ~ 85	°C
Storage Temperature	T_{STG}	–55 ~ +150	°C

Note: Permanent damage may occur if maximum ratings are exceeded. Normal operation should be under recommended operating conditions. If these conditions are exceeded, it could affect reliability.

Bit 2 LNIO. This bit controls the drive capability of certain external I/O pins of the Z8S180/Z8L180. When this bit is set to 1, the output drive capability of the following pins is reduced to 33 percent of the original drive capability:

$\overline{RTS0}$	TxS
CKA1/$\overline{TEND0}$	CKA0/$\overline{DREQ0}$
TXA0	TXA1
$\overline{TENDi}$	CKS

Bit 1 LNCPUCTL. This bit controls the drive capability of the CPU Control pins. When this bit is set to 1, the output drive capability of the following pins is reduced to 33 percent of the original drive capability:

$\overline{BUSACK}$	$\overline{RD}$
$\overline{WR}$	$\overline{M1}$
$\overline{MREQ}$	$\overline{IORQ}$
$\overline{RFSH}$	$\overline{HALT}$
E	TEST
ST	

Bit 0 LNAD/DATA. This bit controls the drive capability of the Address/Data bus output drivers. If this bit is set to 1, the output drive capability of the Address and Data bus outputs is reduced to 33 percent of its original drive capability.

DMA I/O ADDRESS REGISTER

The DMA I/O Address Register specifies the I/O device for channel 1 transfers. This address may be a destination or source I/O device. IAR1L and IAR1H each contain 8 address bits. The most significant byte identifies the Request Handshake signal and controls the Alternating Channel feature.

DMA I/O Address Register Channel 1 Low

Mnemonic IAR1L
Address 2BH

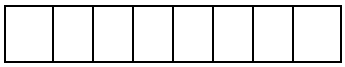

Figure 68. DMA I/O Address Register Channel 1 Low

DMA I/O Address Register Channel 1 High

Mnemonic IAR1H
Address 2CH

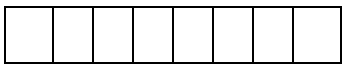

Figure 69. DMA I/O Address Register Channel 1 High

DMA I/O Address Register Channel 1 B

Mnemonic IAR1B
Address 2DH

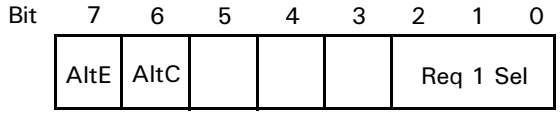

Figure 70. DMA I/O Address Register Channel 1 B

AltE. The AltE bit should be set only when both DMA channels are programmed for the same I/O source or I/O destination. In this case, a *channel end* condition (byte count = 0) on channel 0 sets bit 6 (AltC), which subsequently enables the channel 1 request and blocks the channel 0 request. Similarly, a channel end condition on channel 1 clears bit 6 (AltC), which then enables the channel 0 request and blocks the channel 1 request. For external requests, the request from the device must be routed or connected to both the DREQ0 and DREQ1 pins.

AltC. If bit (AltE) is 0, the AltC bit has no effect. When bit 7 (AltE) is 1 and the AltC bit is 0, the request signal selected by bits 2–0 is not presented to channel 1; however, the channel 0 request operates normally. When AltE is 1 and AltC is 1, the request selected by SAR18–16 or DAR18–16 is not presented to channel 0; however, the channel 1 request operates normally. The AltC bit can be written by software to select which channel should operate first; however, this operation should be executed only when both channels are stopped (both DE1 and DE0 are 0).

Req1Sel. If bit DIM1 in the DCNTL register is 1, indicating an I/O source, the following bits select which source handshake signal should control the transfer:

000	DREQ1 pin
001	ASCI0 RDRF
010	ASCI1 RDRF
Other	Reserved, do not program

If DIM1 is 0, indicating an I/O destination, the following bits select which destination handshake signal should control the transfer:

000	DREQ1 pin
001	ASCI0 TDRE
010	ASCI1 TDRE
Other	Reserved, do not program

DMA STATUS REGISTER

The DMA Status Register (DSTAT) is used to enable and disable DMA transfer and DMA termination interrupts. DSTAT also indicates DMA transfer status, Completed or In Progress.

DMA Status Register

Mnemonic DSTAT
Address 30H

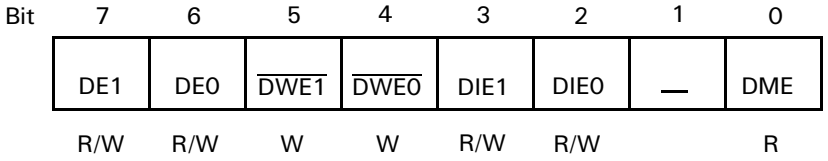

Figure 71. DMA Status Register (DSTAT: I/O Address = 30H)

DE1: DMA Enable Channel 1 (Bit 7). When DE1 = 1 and DME = 1, channel 1 DMA is enabled. When a DMA transfer terminates (BCR1 = 0), DE1 is reset to 0 by the DMAC. When DE1 = 0 and the DMA interrupt is enabled (DIE1 = 1), a DMA interrupt request is made to the CPU.

To perform a software WRITE to DE1, $\overline{\text{DWE1}}$ should be written with a 0 during the same register WRITE access. Writing DE1 to 0 disables channel 1 DMA, but DMA is restartable. Writing DE1 to 1 enables channel 1 DMA and automatically sets DMA Main Enable (DME) to 1. DE1 is cleared to 0 during RESET.

DE0: DMA Enable Channel 0 (Bit 6). When DE0 = 1 and DME = 1, channel 0 DMA is enabled. When a DMA transfer terminates (BCR0 = 0), DE0 is reset to 0 by the DMAC. When DE0 = 0 and the DMA interrupt is enabled (DIE0 = 1), a DMA interrupt request is made to the CPU.

To perform a software WRITE to DE0, $\overline{\text{DWE0}}$ should be written with 0 during the same register WRITE access. Writing DE0 to 0 disables channel 0 DMA. Writing DE0 to 1 enables channel 0 DMA and automatically sets DMA Main Enable (DME) to 1. DE0 is cleared to 0 during RESET.

$\overline{\text{DWE1}}$: DE1 Bit Write Enable (Bit 5). When performing any software WRITE to DE1, this bit should be written with 0 during the same access. $\overline{\text{DWE1}}$ always reads as 1.

$\overline{\text{DWE0}}$: DE0 Bit Write Enable (Bit 4). When performing any software WRITE to DE0, this bit should be written with 0 during the same access. $\overline{\text{DWE0}}$ always reads as 1.

DIE1: DMA Interrupt Enable Channel 1 (Bit 3). When DIE0 is set to 1, the termination channel 1 DMA transfer (indicated when DE1 = 0) causes a CPU interrupt request to be generated. When DIE0 = 0, the channel 0 DMA termination interrupt is disabled. DIE0 is cleared to 0 during RESET.

DIE0: DMA Interrupt Enable Channel 0 (Bit 2). When DIE0 is set to 1, the termination channel 0 of DMA transfer (indicated when DE0 = 0) causes a CPU interrupt request to be generated. When DIE0 = 0, the channel 0 DMA termination interrupt is disabled. DIE0 is cleared to 0 during RESET.

DME: DMA Main Enable (Bit 0). A DMA operation is only enabled when its DE bit (DE0 for channel 0, DE1 for channel 1) and the DME bit is set to 1.

When $\overline{\text{NMI}}$ occurs, DME is reset to 0, thus disabling DMA activity during the $\overline{\text{NMI}}$ interrupt service routine. To restart DMA, DE– and/or DE1 should be written with a 1 (even if the contents are already 1). This condition automatically sets DME to 1, allowing DMA operations to continue.

Note: DME cannot be directly written. The bit is cleared to 0 by $\overline{\text{NMI}}$ or indirectly set to 1 by setting DE0 and/or DE1 to 1. DME is cleared to 0 during RESET.

DMA MODE REGISTER

The DMA Mode Register (DMODE) is used to set the addressing and transfer mode for channel 0.

DMA Mode Register

Mnemonic DMODE
Address 31H

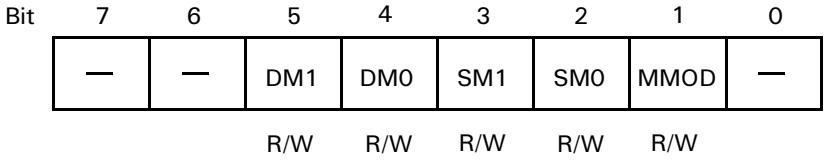

Figure 72. DMA Mode Register (DMODE: I/O Address = 31H)

DM1, DM0: Destination Mode Channel 0 (Bits 5,4). This mode specifies whether the destination for channel 0 transfers is memory or I/O, and whether the address should be incremented or decremented for each byte transferred. DM1 and DM0 are cleared to 0 during RESET.

Table 14. Channel 0 Destination

DM1	DM0	Memory I/O	Memory Increment/Decrement
0	0	Memory	+1
0	1	Memory	–1
1	0	Memory	fixed
1	1	I/O	fixed

SM1, SM0: Source Mode Channel 0 (Bits 3, 2) . This mode specifies whether the source for channel 0 transfers is memory or I/O, and whether the address should be incremented or decremented for each byte transferred.

Table 15. Channel 0 Source

SM1	SM0	Memory I/O	Memory Increment/Decrement
0	0	Memory	+1
0	1	Memory	–1
1	0	Memory	fixed
1	1	I/O	fixed

Table 16 indicates all DMA transfer mode combinations of DM0, DM1, SM0, and SM1. Because I/O to/from I/O transfers are not implemented, 12 combinations are available.

Table 16. Transfer Mode Combinations

DM1	DM0	SM1	SM0	Transfer Mode	Address Increment/Decrement
0	0	0	0	Memory→Memory	SAR0 + 1, DAR0 + 1
0	0	0	1	Memory→Memory	SAR0–1, DAR0 + 1
0	0	1	0	Memory*→Memory	SAR0 fixed, DAR0 + 1
0	0	1	1	I/O→Memory	SAR0 fixed, DAR0 + 1
0	1	0	0	Memory→Memory	SAR0 + 1, DAR0–1
0	1	0	1	Memory→Memory	SAR0–1, DAR0–1
0	1	1	0	Memory*→Memory	SAR0 fixed, DAR0–1
0	1	1	1	I/O→Memory	SAR0 fixed, DAR0–1
1	0	0	0	Memory→Memory*	SAR0 + 1, DAR0 fixed
1	0	0	1	Memory→Memory*	SAR0–1, DAR0 fixed
1	0	1	0	Reserved	
1	0	1	1	Reserved	
1	1	0	0	Memory→I/O	SAR0 + 1, DAR0 fixed
1	1	0	1	Memory→I/O	SAR0–1, DAR0 fixed
1	1	1	0	Reserved	
1	1	1	1	Reserved	

Note: * Includes memory mapped I/O.

MMOD: Memory Mode Channel 0 (Bit 1). When channel 0 is configured for memory to/from memory transfers there is no Request Handshake signal to control the transfer timing. Instead, two automatic transfer timing modes are selectable: burst (MMOD = 1) and cycle steal (MMOD = 0). For burst memory to/from memory transfers, the DMAC takes control of the bus continuously until the DMA transfer completes (as indicated by the byte count register = 0). In cycle steal mode, the CPU is provided a cycle for each DMA byte transfer cycle until the transfer is completed.

For channel 0 DMA with I/O source or destination, the selected Request signal times the transfer ignoring MMOD. MMOD is cleared to 0 during RESET.

DMA/WAIT CONTROL REGISTER

The DMA/WAIT Control Register (DCNTL) controls the insertion of wait states into DMAC (and CPU) accesses of memory or I/O. Also, the register defines the Request signal for each channel as level or edge sense. DCNTL also sets the DMA transfer mode for channel 1, which is limited to memory to/from I/O transfers.

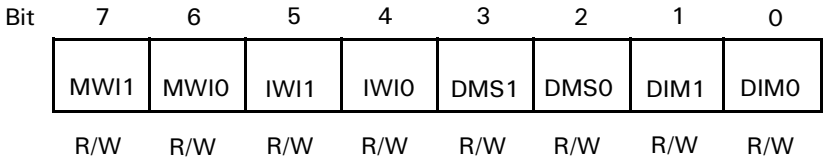

Figure 73. DMA/WAIT Control Register (DCNTL: I/O Address = 32H)

MWI1, MWI0: Memory Wait Insertion (Bits 7–6). This bit specifies the number of wait states introduced into CPU or DMAC memory access cycles. MWI1 and MWI0 are set to 1 during RESET.

MWI1	MWI0	Wait State
0	0	0
0	1	1
1	0	2
1	1	3

IWI1, IWI0: I/O Wait Insertion (Bits 5–4). This bit specifies the number of wait states introduced into CPU or DMAC I/O access cycles. IWI1 and IWI0 are set to 1 during RESET.

IWI1	IWI0	Wait State
0	0	1
0	1	2
1	0	3
1	1	4

Note: These wait states are added to the 3-clock I/O cycle that is used to access the on-chip I/O registers. It is equally valid to regard these as 0 to 3 wait states added to a 4-clock external I/O cycle.

DMS1, DMS0: DMA Request Sense (Bits 3–2). DMS1 and DMS0 specify the DMA request sense for channel 0 and channel 1 respectively. When reset to 0, the input is level sense. When set to 1, the input is edge sense. DMS1 and DMS0 are cleared to 0 during RESET.

DMSi	Sense
1	Edge Sense
0	Level Sense

Typically, for an input/source device, the associated DMS bit should be programmed as 0 for level sense. The device takes a relatively long time to update its Request signal after the DMA channel reads data (in the first of the two machine cycles involved in transferring a byte).

An output/destination device takes much less time to update its Request signal after the DMA channel starts a WRITE operation to it (the second machine cycle of the two cycles involved in transferring a byte). With zero-wait state I/O cycles, a device cannot update its request signal in the required time, so edge sensing must be used.

A one-wait-state I/O cycle also does not provide sufficient time for updating, so edge sensing is again required.

DIM1, DIM0: DMA Channel 1 I/O and Memory Mode (Bits 1–0). Specifies the source/destination and address modifier for channel 1 memory to/from I/O transfer modes. DIM1 and DIM0 are cleared to 0 during RESET.

Table 17. Channel 1 Transfer Mode

DIM1	DMI0	Transfer Mode	Address Increment/Decrement
0	0	Memory→I/O	MAR1 +1, IAR1 fixed
0	1	Memory→I/O	MAR1 –1, IAR1 fixed
1	0	I/O→Memory	IAR1 fixed, MAR1 +1
1	1	I/O→Memory	IAR1 fixed, MAR1 –1
