
What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	eZ8
Core Size	8-Bit
Speed	20MHz
Connectivity	I²C, IrDA, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, DMA, POR, PWM, WDT
Number of I/O	31
Program Memory Size	32KB (32K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	2K x 8
Voltage - Supply (Vcc/Vdd)	3V ~ 3.6V
Data Converters	A/D 8x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 105°C (TA)
Mounting Type	Surface Mount
Package / Case	44-LQFP
Supplier Device Package	44-LQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8f3221an020ec

SPIENL—SPI Interrupt Request Enable Low Bit
ADCENL—ADC Interrupt Request Enable Low Bit

IRQ1 Enable High and Low Bit Registers

The IRQ1 Enable High and Low Bit registers (see Table 31 and Table 32 on page 76) form a priority encoded enabling for interrupts in the Interrupt Request 1 register. Priority is generated by setting bits in each register. Table 30 describes the priority control for IRQ1.

Table 30. IRQ1 Enable and Priority Encoding

IRQ1ENH[*x*]	IRQ1ENL[*x*]	Priority	Description
0	0	Disabled	Disabled
0	1	Level 1	Low
1	0	Level 2	Nominal
1	1	Level 3	High

Note: where *x* indicates the register bits from 0 through 7.

One-Shot time-out, first set the `TPOL` bit in the Timer Control 1 Register to the start value before beginning ONE-SHOT mode. Then, after starting the timer, set `TPOL` to the opposite bit value.

Follow the steps below for configuring a timer for ONE-SHOT mode and initiating the count:

1. Write to the Timer Control 1 register to:
   – Disable the timer
   – Configure the timer for ONE-SHOT mode
   – Set the prescale value
   – If using the Timer Output alternate function, set the initial output level (High or Low)
2. Write to the Timer High and Low Byte registers to set the starting count value
3. Write to the Timer Reload High and Low Byte registers to set the Reload value
4. If desired, enable the timer interrupt and set the timer interrupt priority by writing to the relevant interrupt registers
5. If using the Timer Output function, configure the associated GPIO port pin for the Timer Output alternate function
6. Write to the Timer Control 1 register to enable the timer and initiate counting

In ONE-SHOT mode, the system clock always provides the timer input. The timer period is given by the following equation:

$$\text{ONE-SHOT Mode Time-Out Period (s)} = \frac{(\text{Reload Value} - \text{Start Value}) \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

CONTINUOUS Mode

In CONTINUOUS mode, the timer counts up to the 16-bit Reload value stored in the Timer Reload High and Low Byte registers. The timer input is the system clock. Upon reaching the Reload value, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to `0001H` and counting resumes. Also, if the Timer Output alternate function is enabled, the Timer Output pin changes state (from Low to High or from High to Low) upon timer Reload.

Follow the steps below for configuring a timer for CONTINUOUS mode and initiating the count:

1. Write to the Timer Control 1 register to:
   – Disable the timer
   – Configure the timer for CONTINUOUS mode
   – Set the prescale value
   – If using the Timer Output alternate function, set the initial output level (High or Low)

Follow the steps below for configuring a timer for PWM mode and initiating the PWM operation:

1. Write to the Timer Control 1 register to:
   - Disable the timer
   - Configure the timer for PWM mode
   - Set the prescale value
   - Set the initial logic level (High or Low) and PWM High/Low transition for the Timer Output alternate function
2. Write to the Timer High and Low Byte registers to set the starting count value (typically `0001H`). This only affects the first pass in PWM mode. After the first timer reset in PWM mode, counting always begins at the reset value of `0001H`.
3. Write to the PWM High and Low Byte registers to set the PWM value.
4. Write to the Timer Reload High and Low Byte registers to set the Reload value (PWM period). The Reload value must be greater than the PWM value.
5. If desired, enable the timer interrupt and set the timer interrupt priority by writing to the relevant interrupt registers.
6. Configure the associated GPIO port pin for the Timer Output alternate function.
7. Write to the Timer Control 1 register to enable the timer and initiate counting.

The PWM period is given by the following equation:

$$\text{PWM Period (s)} = \frac{\text{Reload Value} \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

If an initial starting value other than `0001H` is loaded into the Timer High and Low Byte registers, the ONE-SHOT mode equation must be used to determine the first PWM time-out period.

If `TPOL` is set to 0, the ratio of the PWM output High time to the total period is given by:

$$\text{PWM Output High Time Ratio (\%)} = \frac{\text{Reload Value} - \text{PWM Value}}{\text{Reload Value}} \times 100$$

If `TPOL` is set to 1, the ratio of the PWM output High time to the total period is given by:

$$\text{PWM Output High Time Ratio (\%)} = \frac{\text{PWM Value}}{\text{Reload Value}} \times 100$$

CAPTURE Mode

In CAPTURE mode, the current timer count value is recorded when the desired external Timer Input transition occurs. The Capture count value is written to the Timer PWM High and Low Byte Registers. The timer input is the system clock. The `TPOL` bit in the Timer Control 1 register determines if the Capture occurs on a rising edge or a falling edge of the Timer Input signal. When the Capture event occurs, an interrupt is generated and the timer continues counting.

Table 42. Timer 0-3 Reload Low Byte Register (TxRL)

BITS	7	6	5	4	3	2	1	0
FIELD	TRL							
RESET	1							
R/W	R/W

TRH and TRL—Timer Reload Register High and Low
These two bytes form the 16-bit Reload value, {TRH[7:0], TRL[7:0]}. This value sets the maximum count value which initiates a timer reload to `0001H`. In COMPARE mode, these two byte form the 16-bit Compare value.

Timer 0-3 PWM High and Low Byte Registers

The Timer 0-3 PWM High and Low Byte (TxPWMH and TxPWML) registers (see Table 43 and Table 44 on page 92) are used for Pulse-Width Modulator (PWM) operations. These registers also store the Capture values for the Capture and Capture/COMPARE modes.

4. The I²C Controller sends the START condition.
5. The I²C Controller shifts the address and read bit out the SDA signal.
6. If the I²C slave acknowledges the address by pulling the SDA signal Low during the next high period of SCL, the I²C Controller sets the ACK bit in the I²C Status register. Continue with step 7.

   If the slave does not acknowledge, the Not Acknowledge interrupt occurs (NCKI bit is set in the Status register, ACK bit is cleared). Software responds to the Not Acknowledge interrupt by setting the STOP bit and clearing the TXI bit. The I²C Controller sends the STOP condition on the bus and clears the STOP and NCKI bits. The transaction is complete (ignore the following steps).
7. The I²C Controller shifts in the byte of data from the I²C slave on the SDA signal. The I²C Controller sends a Not Acknowledge to the I²C slave if the NAK bit is set (last byte), else it sends an Acknowledge.
8. The I²C Controller asserts the Receive interrupt (RDRF bit set in the Status register).
9. Software responds by reading the I²C Data register which clears the RDRF bit. If there is only one more byte to receive, set the NAK bit of the I²C Control register.
10. If there are more bytes to transfer, return to step 7.
11. After the last byte is shifted in, a Not Acknowledge interrupt is generated by the I²C Controller.
12. Software responds by setting the `STOP` bit of the I²C Control register.
13. A STOP condition is sent to the I²C slave, the STOP and NCKI bits are cleared.

Read Transaction with a 10-Bit Address

Figure 33 displays the read transaction format for a 10-bit addressed slave. The shaded regions indicate data transferred from the I²C Controller to slaves and unshaded regions indicate data transferred from the slaves to the I²C Controller.

S	Slave Address 1st 7 bits	W=0	A	Slave Address 2nd Byte	A	S	Slave Address 1st 7 bits	R=1	A	Data	A	Data	$\overline{A}$	P

Figure 33. Receive Data Format for a 10-Bit Addressed Slave

The first seven bits transmitted in the first byte are `11110XX`. The two bits `XX` are the two most-significant bits of the 10-bit address. The lowest bit of the first byte transferred is the write control bit.

Table 88. ADC Data Low Bits Register (ADCD_L)

Reserved
These Option Bits are reserved for future use and must always be 1. This setting is the default for unprogrammed (erased) Flash.

OCD Serial Errors

The On-Chip Debugger can detect any of the following error conditions on the DBG pin:

- Serial Break (a minimum of nine continuous bits Low).
- Framing Error (received Stop bit is Low).
- Transmit Collision (OCD and host simultaneous transmission detected by the OCD).

When the OCD detects one of these errors, it aborts any command currently in progress, transmits a Serial Break 4096 system clock cycles long back to the host, and resets the Auto-Baud Detector/Generator. A Framing Error or Transmit Collision may be caused by the host sending a Serial Break to the OCD. Because of the open-drain nature of the interface, returning a Serial Break break back to the host only extends the length of the Serial Break if the host releases the Serial Break early.

The host transmits a Serial Break on the DBG pin when first connecting to the 64K Series devices or when recovering from an error. A Serial Break from the host resets the Auto-Baud Generator/Detector but does not reset the OCD Control register. A Serial Break leaves the device in DEBUG mode if that is the current mode. The OCD is held in Reset until the end of the Serial Break when the DBG pin returns High. Because of the open-drain nature of the DBG pin, the host can send a Serial Break to the OCD even if the OCD is transmitting a character.

Breakpoints

Execution Breakpoints are generated using the BRK instruction (opcode 00H). When the eZ8 CPU decodes a BRK instruction, it signals the On-Chip Debugger. If Breakpoints are enabled, the OCD idles the eZ8 CPU and enters DEBUG mode. If Breakpoints are not enabled, the OCD ignores the BRK signal and the BRK instruction operates as an NOP.

If breakpoints are enabled, the OCD can be configured to automatically enter DEBUG mode, or to loop on the break instruction. If the OCD is configured to loop on the BRK instruction, then the CPU is still enabled to service DMA and interrupt requests.

The loop on BRK instruction can be used to service interrupts in the background. For interrupts to be serviced in the background, there cannot be any breakpoints in the interrupt service routine. Otherwise, the CPU stops on the breakpoint in the interrupt routine. For interrupts to be serviced in the background, interrupts must also be enabled. Debugging software should not automatically enable interrupts when using this feature, since interrupts are typically disabled during critical sections of code where interrupts should not occur (such as adjusting the stack pointer or modifying shared data).

Software can poll the IDLE bit of the OCDSTAT register to determine if the OCD is looping on a BRK instruction. When software wants to stop the CPU on the BRK instruction it is looping on, software should not set the DBGMODE bit of the OCDCTL register. The CPU may have vectored to and be in the middle of an interrupt service routine when this bit gets set. Instead, software must clear the BRKLP bit. This action allows the CPU to

Figure 45 displays the typical current consumption in HALT mode while operating at 25 ºC versus the system clock frequency. All GPIO pins are configured as outputs and driven High.

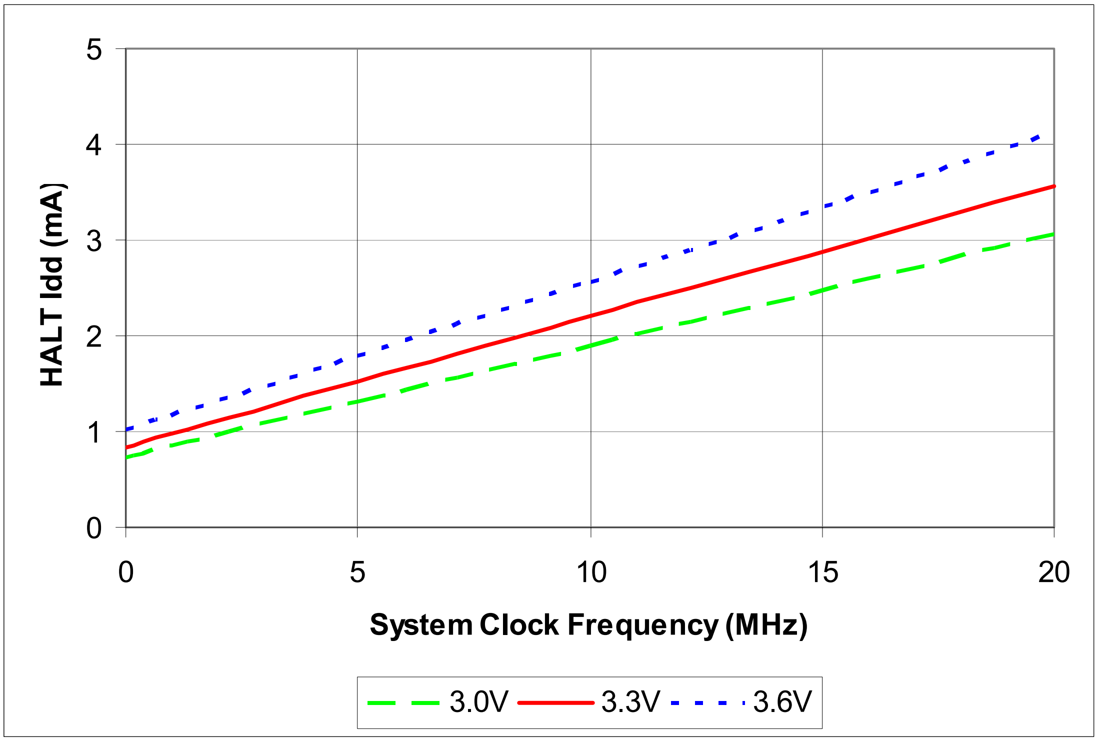

Figure 45. Typical HALT Mode Idd Versus System Clock Frequency

AC Characteristics

The section provides information on the AC characteristics and timing. All AC timing information assumes a standard load of 50 pF on all outputs. Table 113 lists the 64K Series AC characteristics and timing.

Table 113. AC Characteristics

Symbol	Parameter	V_{DD} = 3.0–3.6V T_A = –40 °C to 125 °C Minimum	Maximum	Units	Conditions
F_{sysclk}	System Clock Frequency	–	20.0	MHz	Read-only from Flash memory.
		0.032768	20.0	MHz	Program or erasure of the Flash memory.
F_{XTAL}	Crystal Oscillator Frequency	0.032768	20.0	MHz	System clock frequencies below the crystal oscillator minimum require an external clock driver.
T_{XIN}	Crystal Oscillator Clock Period	50	–	ns	$T_{CLK} = 1/F_{sysclk}$
T_{XINH}	System Clock High Time	20		ns	
T_{XINL}	System Clock Low Time	20		ns	
T_{XINR}	System Clock Rise Time	–	3	ns	T_{CLK} = 50 ns. Slower rise times can be tolerated with longer clock periods.
T_{XINF}	System Clock Fall Time	–	3	ns	T_{CLK} = 50 ns. Slower fall times can be tolerated with longer clock periods.
