
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	dsPIC
Core Size	16-Bit
Speed	20 MIPS
Connectivity	CANbus, I²C, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, Motor Control PWM, QEI, POR, PWM, WDT
Number of I/O	20
Program Memory Size	48KB (16K x 24)
Program Memory Type	FLASH
EEPROM Size	1K x 8
RAM Size	2K x 8
Voltage - Supply (Vcc/Vdd)	2.5V ~ 5.5V
Data Converters	A/D 6x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 125°C (TA)
Mounting Type	Through Hole
Package / Case	28-DIP (0.300", 7.62mm)
Supplier Device Package	28-SPDIP
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/dspic30f4012-20e-sp

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

Table 1-2 provides a brief description of the device I/O pinout and the functions that are multiplexed to a port pin. Multiple functions may exist on one port pin. When multiplexing occurs, the peripheral module’s functional requirements may force an override of the data direction of the port pin.

TABLE 1-2: dsPIC30F4012 I/O PIN DESCRIPTIONS

Pin Name	Pin Type	Buffer Type	Description
AN0-AN5	I	Analog	Analog input channels. AN0 and AN1 are also used for device programming data and clock inputs, respectively.
AVDD	P	P	Positive supply for analog module. This pin must be connected at all times.
AVSS	P	P	Ground reference for analog module. This pin must be connected at all times.
CLKI CLKO	I O	ST/CMOS —	External clock source input. Always associated with OSC1 pin function. Oscillator crystal output. Connects to crystal or resonator in Crystal Oscillator mode. Optionally functions as CLKO in RC and EC modes. Always associated with OSC2 pin function.
CN0-CN7	I	ST	Input change notification inputs. Can be software programmed for internal weak pull-ups on all inputs.
C1RX C1TX	I O	ST —	CAN1 bus receive pin. CAN1 bus transmit pin.
EMUD EMUC EMUD1 EMUC1 EMUD2 EMUC2 EMUD3 EMUC3	I/O I/O I/O I/O I/O I/O I/O I/O	ST ST ST ST ST ST ST ST	ICD Primary Communication Channel data input/output pin. ICD Primary Communication Channel clock input/output pin. ICD Secondary Communication Channel data input/output pin. ICD Secondary Communication Channel clock input/output pin. ICD Tertiary Communication Channel data input/output pin. ICD Tertiary Communication Channel clock input/output pin. ICD Quaternary Communication Channel data input/output pin. ICD Quaternary Communication Channel clock input/output pin.
IC1, IC2, IC7, IC8	I	ST	Capture inputs 1, 2, 7 and 8.
INDX QEA QEB	I I I	ST ST ST	Quadrature Encoder Index Pulse input. Quadrature Encoder Phase A input in QEI mode. Auxiliary Timer External Clock/Gate input in Timer mode. Quadrature Encoder Phase B input in QEI mode. Auxiliary Timer External Clock/Gate input in Timer mode.
INT0 INT1 INT2	I I I	ST ST ST	External interrupt 0. External interrupt 1. External interrupt 2.
$\overline{\mathrm{FLTA}}$ PWM1L PWM1H PWM2L PWM2H PWM3L PWM3H	I O O O O O O	ST — — — — — —	PWM Fault A input. PWM1 low output. PWM1 high output. PWM2 low output. PWM2 high output. PWM3 low output. PWM3 high output.
$\overline{\mathrm{MCLR}}$	I/P	ST	Master Clear (Reset) input or programming voltage input. This pin is an active-low Reset to the device.
OCFA OC1, OC2	I O	ST —	Compare Fault A input (for Compare channels 1, 2, 3 and 4). Compare outputs 1 and 2.

Legend:

CMOS	=	CMOS compatible input or output	Analog	=	Analog input
ST	=	Schmitt Trigger input with CMOS levels	O	=	Output
I	=	Input	P	=	Power

2.4.1 MULTIPLIER

The 17x17-bit multiplier is capable of signed or unsigned operation and can multiplex its output using a scaler to support either 1.31 fractional (Q31) or 32-bit integer results. Unsigned operands are zero-extended into the 17th bit of the multiplier input value. Signed operands are sign-extended into the 17th bit of the multiplier input value. The output of the 17x17-bit multiplier/scaler is a 33-bit value, which is sign-extended to 40 bits. Integer data is inherently represented as a signed two's complement value, where the MSB is defined as a sign bit. Generally speaking, the range of an N-bit two's complement integer is -2^{N-1} to $2^{N-1} - 1$. For a 16-bit integer, the data range is -32768 (0x8000) to 32767 (0x7FFF), including 0. For a 32-bit integer, the data range is -2,147,483,648 (0x8000 0000) to 2,147,483,645 (0x7FFF FFFF).

When the multiplier is configured for fractional multiplication, the data is represented as a two's complement fraction, where the MSB is defined as a sign bit and the radix point is implied to lie just after the sign bit (QX format). The range of an N-bit two's complement fraction with this implied radix point is -1.0 to $(1-2^{1-N})$. For a 16-bit fraction, the Q15 data range is -1.0 (0x8000) to 0.999969482 (0x7FFF), including 0, and has a precision of 3.01518×10^{-5}. In Fractional mode, a 16x16 multiply operation generates a 1.31 product, which has a precision of 4.65661×10^{-10}.

The same multiplier is used to support the DSC multiply instructions, which include integer 16-bit signed, unsigned and mixed sign multiplies.

The `MUL` instruction may be directed to use byte or word-sized operands. Byte operands direct a 16-bit result, and word operands direct a 32-bit result to the specified register(s) in the W array.

2.4.2 DATA ACCUMULATORS AND ADDER/SUBTRACTER

The data accumulator consists of a 40-bit adder/subtracter with automatic sign extension logic. It can select one of two accumulators (A or B) as its pre-accumulation source and post-accumulation destination. For the `ADD` and `LAC` instructions, the data to be accumulated or loaded can be optionally scaled via the barrel shifter, prior to accumulation.

2.4.2.1 Adder/Subtracter, Overflow and Saturation

The adder/subtracter is a 40-bit adder with an optional zero input into one side and either true or complement data into the other input. In the case of addition, the carry/borrow input is active-high and the other input is true data (not complemented), whereas in the case of subtraction, the carry/borrow input is active-low and the other input is complemented. The adder/subtracter generates Overflow Status bits, SA/SB and OA/OB, which are latched and reflected in the STATUS register.

- Overflow from bit 39: this is a catastrophic overflow in which the sign of the accumulator is destroyed.
- Overflow into guard bits 32 through 39: this is a recoverable overflow. This bit is set whenever all the guard bits are not identical to each other.

The adder has an additional saturation block which controls accumulator data saturation, if selected. It uses the result of the adder, the Overflow Status bits described above, and the SATA/B (CORCON<7:6>) and ACCSAT (CORCON<4>) mode control bits to determine when and to what value to saturate.

Six STATUS register bits have been provided to support saturation and overflow; they are:

1. OA: ACCA overflowed into guard bits.
2. OB: ACCB overflowed into guard bits.
3. SA: ACCA saturated (bit 31 overflow and saturation).
   or
   ACCA overflowed into guard bits and saturated (bit 39 overflow and saturation).
4. SB: ACCB saturated (bit 31 overflow and saturation).
   or
   ACCB overflowed into guard bits and saturated (bit 39 overflow and saturation).
5. OAB: Logical OR of OA and OB.
6. SAB: Logical OR of SA and SB.

The OA and OB bits are modified each time data passes through the adder/subtracter. When set, they indicate that the most recent operation has overflowed into the accumulator guard bits (bits 32 through 39). Also, the OA and OB bits can optionally generate an arithmetic warning trap when set and the corresponding Overflow Trap Flag Enable bit (OVATE, OVBTE) in the INTCON1 register (refer to **Section 5.0 "Interrupts"**) is set. This allows the user to take immediate action, for example, to correct system gain.

© 2010 Microchip Technology Inc.

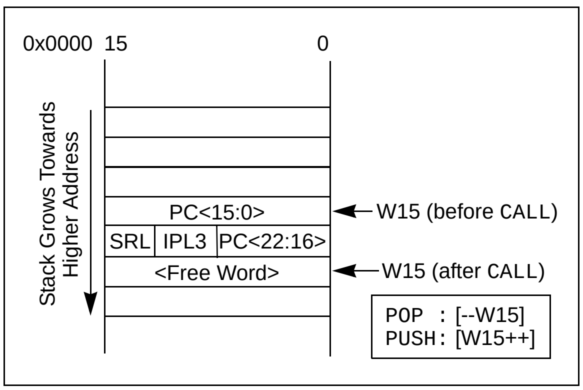
5.4 Interrupt Sequence

All interrupt event flags are sampled in the beginning of each instruction cycle by the IFSx registers. A pending interrupt request (IRQ) is indicated by the flag bit being equal to a ‘1’ in an IFSx register. The IRQ will cause an interrupt to occur if the corresponding bit in the interrupt enable (IECx) register is set. For the remainder of the instruction cycle, the priorities of all pending interrupt requests are evaluated.

If there is a pending IRQ with a priority level greater than the current processor priority level in the IPL bits, the processor will be interrupted.

The processor then stacks the current program counter and the low byte of the processor STATUS register (SRL), as shown in Figure 5-2. The low byte of the STATUS register contains the processor priority level at the time prior to the beginning of the interrupt cycle. The processor then loads the priority level for this interrupt into the STATUS register. This action will disable all lower priority interrupts until the completion of the Interrupt Service Routine (ISR).

FIGURE 5-2: INTERRUPT STACK FRAME



> **Note 1:** The user can always lower the priority level by writing a new value into SR. The Interrupt Service Routine must clear the interrupt flag bits in the IFSx register before lowering the processor interrupt priority in order to avoid recursive interrupts.
>
> **2:** The IPL3 bit (CORCON<3>) is always clear when interrupts are being processed. It is set only during execution of traps.

The `RETFIE` (return from interrupt) instruction will unstack the program counter and STATUS registers to return the processor to its state prior to the interrupt sequence.

5.5 Alternate Interrupt Vector Table

In program memory, the Interrupt Vector Table (IVT) is followed by the Alternate Interrupt Vector Table (AIVT), as shown in Figure 5-1. Access to the Alternate Interrupt Vector Table is provided by the ALTIVT bit in the INTCON2 register. If the ALTIVT bit is set, all interrupt and exception processes will use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors. The AIVT supports emulation and debugging efforts by providing a means to switch between an application and a support environment, without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run time.

If the AIVT is not required, the program memory allocated to the AIVT may be used for other purposes. AIVT is not a protected section and may be freely programmed by the user.

5.6 Fast Context Saving

A context saving option is available using shadow registers. Shadow registers are provided for the DC, N, OV, Z and C bits in SR, and the registers W0 through W3. The shadows are only one-level deep. The shadow registers are accessible using the `PUSH.S` and `POP.S` instructions only.

When the processor vectors to an interrupt, the `PUSH.S` instruction can be used to store the current value of the aforementioned registers into their respective shadow registers.

If an ISR of a certain priority uses the `PUSH.S` and `POP.S` instructions for fast context saving, then a higher priority ISR should not include the same instructions. Users must save the key registers in software during a lower priority interrupt if the higher priority ISR uses fast context saving.

5.7 External Interrupt Requests

The interrupt controller supports three external interrupt request signals, INT0-INT2. These inputs are edge sensitive; they require a low-to-high, or a high-to-low transition, to generate an interrupt request. The INTCON2 register has three bits, INT0EP-INT2EP, that select the polarity of the edge detection circuitry.

5.8 Wake-up from Sleep and Idle

The interrupt controller may be used to wake-up the processor from either Sleep or Idle modes if Sleep or Idle modes are active when the interrupt is generated.

If an enabled interrupt request of sufficient priority is received by the interrupt controller, then the standard interrupt request is presented to the processor. At the same time, the processor will wake-up from Sleep or Idle and begin execution of the ISR needed to process the interrupt request.

12.0 INPUT CAPTURE MODULE

> **Note:** This data sheet summarizes features of this group of dsPIC30F devices and is not intended to be a complete reference source. For more information on the CPU, peripherals, register descriptions and general device functionality, refer to the *dsPIC30F Family Reference Manual* (DS70046). For more information on the device instruction set and programming, refer to the *"16-bit MCU and DSC Reference Manual"* (DS70157).

This section describes the input capture module and associated operational modes. The features provided by this module are useful in applications requiring frequency (period) and pulse measurement. Figure 12-1 depicts a block diagram of the input capture module. Input capture is useful for such modes as:

- Frequency/Period/Pulse Measurements
- Additional Sources of External Interrupts

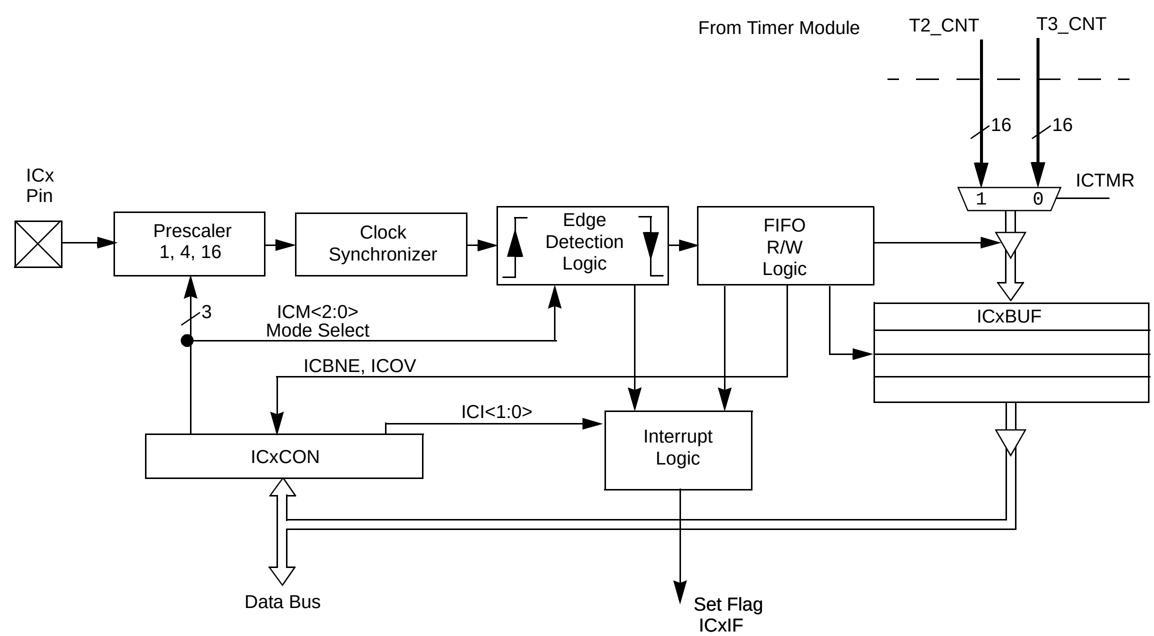
The key operational features of the input capture module are:

- Simple Capture Event mode
- Timer2 and Timer3 mode selection
- Interrupt on input capture event

These operating modes are determined by setting the appropriate bits in the ICxCON register (where x = 1, 2, ...N). The dsPIC30F4011/4012 devices have four capture channels.

> **Note:** The dsPIC30F4011/4012 devices have four capture inputs: IC1, IC2, IC7 and IC8. The naming of these four capture channels is intentional and preserves software compatibility with other dsPIC Digital Signal Controllers.

FIGURE 12-1: INPUT CAPTURE MODE BLOCK DIAGRAM



Note: Where 'x' is shown, reference is made to the registers or bits associated to the respective input capture channels 1 through N.

15.1 PWM Time Base

The PWM time base is provided by a 15-bit timer with a prescaler and postscaler. The time base is accessible via the PTMR SFR. PTMR<15> is a read-only status bit, PTDIR, that indicates the present count direction of the PWM time base. If PTDIR is cleared, PTMR is counting upwards. If PTDIR is set, PTMR is counting downwards. The PWM time base is configured via the PTCON SFR. The time base is enabled/disabled by setting/clearing the PTEN bit in the PTCON SFR. PTMR is not cleared when the PTEN bit is cleared in software.

The PTPER SFR sets the counting period for PTMR. The user must write a 15-bit value to PTPER<14:0>. When the value in PTMR<14:0> matches the value in PTPER<14:0>, the time base will either reset to '0', or reverse the count direction on the next occurring clock cycle. The action taken depends on the operating mode of the time base.

> **Note:** If the Period register is set to 0x0000, the timer will stop counting, and the interrupt and special event trigger will not be generated even if the special event value is also 0x0000. The module will not update the Period register if it is already at 0x0000; therefore, the user must disable the module in order to update the Period register.

The PWM time base can be configured for four different modes of operation:

- Free-Running mode
- Single-Shot mode
- Continuous Up/Down Count mode
- Continuous Up/Down Count mode with interrupts for double updates

These four modes are selected by the PTMOD<1:0> bits in the PTCON SFR. The Continuous Up/Down Count modes support center-aligned PWM generation. The Single-Shot mode allows the PWM module to support pulse control of certain Electronically Commutative Motors (ECMs).

The interrupt signals generated by the PWM time base depend on the mode selection bits (PTMOD<1:0>) and the postscaler bits (PTOPS<3:0>) in the PTCON SFR.

15.1.1 FREE-RUNNING MODE

In the Free-Running mode, the PWM time base counts upwards until the value in the Time Base Period register (PTPER) is matched. The PTMR register is reset on the following input clock edge and the time base will continue to count upwards as long as the PTEN bit remains set.

When the PWM time base is in the Free-Running mode (PTMOD<1:0> = 00), an interrupt event is generated each time a match with the PTPER register occurs and the PTMR register is reset to zero. The postscaler selection bits may be used in this mode of the timer to reduce the frequency of the interrupt events.

15.1.2 SINGLE-SHOT MODE

In the Single-Shot mode, the PWM time base begins counting upwards when the PTEN bit is set. When the value in the PTMR register matches the PTPER register, the PTMR register will be reset on the following input clock edge and the PTEN bit will be cleared by the hardware to halt the time base.

When the PWM time base is in the Single-Shot mode (PTMOD<1:0> = 01), an interrupt event is generated when a match with the PTPER register occurs, the PTMR register is reset to zero on the following input clock edge and the PTEN bit is cleared. The postscaler selection bits have no effect in this mode of the timer.

15.1.3 CONTINUOUS UP/DOWN COUNT MODES

In the Continuous Up/Down Count modes, the PWM time base counts upwards until the value in the PTPER register is matched. The timer will begin counting downwards on the following input clock edge. The PTDIR bit in the PTMR SFR is read-only and indicates the counting direction. The PTDIR bit is set when the timer counts downwards.

In the Continuous Up/Down Count mode (PTMOD<1:0> = 10), an interrupt event is generated each time the value of the PTMR register becomes zero and the PWM time base begins to count upwards. The postscaler selection bits may be used in this mode of the timer to reduce the frequency of the interrupt events.

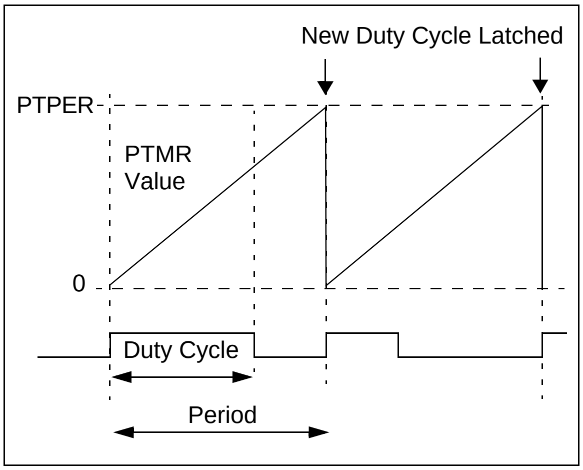
© 2010 Microchip Technology Inc.

15.3 Edge-Aligned PWM

Edge-aligned PWM signals are produced by the module when the PWM time base is in the Free-Running or Single-Shot mode. For edge-aligned PWM outputs, the output has a period specified by the value in PTPER and a duty cycle specified by the appropriate duty cycle register (see Figure 15-2). The PWM output is driven active at the beginning of the period (PTMR = 0) and is driven inactive when the value in the duty cycle register matches PTMR.

If the value in a particular duty cycle register is zero, then the output on the corresponding PWM pin will be inactive for the entire PWM period. In addition, the output on the PWM pin will be active for the entire PWM period if the value in the duty cycle register is greater than the value held in the PTPER register.

FIGURE 15-2: EDGE-ALIGNED PWM



15.4 Center-Aligned PWM

Center-aligned PWM signals are produced by the module when the PWM time base is configured in a Continuous Up/Down Count mode (see Figure 15-3).

The PWM compare output is driven to the active state when the value of the duty cycle register matches the value of PTMR and the PWM time base is counting downwards (PTDIR = 1). The PWM compare output is driven to the inactive state when the PWM time base is counting upwards (PTDIR = 0) and the value in the PTMR register matches the duty cycle value.

If the value in a particular duty cycle register is zero, then the output on the corresponding PWM pin will be inactive for the entire PWM period. In addition, the output on the PWM pin will be active for the entire PWM period if the value in the duty cycle register is equal to the value held in the PTPER register.

FIGURE 15-3: CENTER-ALIGNED PWM

19.4.6.3 Receive Error Interrupts

A receive error interrupt will be indicated by the ERRIF bit. This bit shows that an error condition occurred. The source of the error can be determined by checking the bits in the CAN Interrupt Status register, C1INTF.

- Invalid message received.
- If any type of error occurred during reception of the last message, an error will be indicated by the IVRIF bit.
- Receiver overrun.
- The RXxOVR bit indicates that an overrun condition occurred.
- Receiver warning.
- The RXWAR bit indicates that the Receive Error Counter (RERRCNT<7:0>) has reached the warning limit of 96.
- Receiver error passive.
- The RXEP bit indicates that the Receive Error Counter has exceeded the error passive limit of 127 and the module has gone into error passive state.

19.5 Message Transmission

19.5.1 TRANSMIT BUFFERS

The CAN module has three transmit buffers. Each of the three buffers occupies 14 bytes of data. Eight of the bytes are the maximum 8 bytes of the transmitted message. Five bytes hold the standard and extended identifiers and other message arbitration information.

19.5.2 TRANSMIT MESSAGE PRIORITY

Transmit priority is a prioritization within each node of the pending transmittable messages. There are 4 levels of transmit priority. If TXPRI<1:0> (C1TXxCON<1:0>, where x = 0, 1 or 2, represents a particular transmit buffer) for a particular message buffer is set to ‘11’, that buffer has the highest priority. If TXPRI<1:0> for a particular message buffer is set to ‘10’ or ‘01’, that buffer has an intermediate priority. If TXPRI<1:0> for a particular message buffer is ‘00’, that buffer has the lowest priority.

19.5.3 TRANSMISSION SEQUENCE

To initiate transmission of the message, the TXREQ bit (C1TXxCON<3>) must be set. The CAN bus module resolves any timing conflicts between setting of the TXREQ bit and the Start-of-Frame (SOF), ensuring that if the priority was changed, it is resolved correctly before the SOF occurs. When TXREQ is set, the TXABT (C1TXxCON<6>), TXLARB (C1TXxCON<5>) and TXERR (C1TXxCON<4>) flag bits are automatically cleared.

Setting TXREQ bit simply flags a message buffer as enqueued for transmission. When the module detects an available bus, it begins transmitting the message which has been determined to have the highest priority.

If the transmission completes successfully on the first attempt, the TXREQ bit is cleared automatically and an interrupt is generated if TXxIE was set.

If the message transmission fails, one of the error condition flags will be set and the TXREQ bit will remain set, indicating that the message is still pending for transmission. If the message encountered an error condition during the transmission attempt, the TXERR bit will be set and the error condition may cause an interrupt. If the message loses arbitration during the transmission attempt, the TXLARB bit is set. No interrupt is generated to signal the loss of arbitration.

19.5.4 ABORTING MESSAGE TRANSMISSION

The system can also abort a message by clearing the TXREQ bit associated with each message buffer. Setting the ABAT bit (C1CTRL<12>) will request an abort of all pending messages. If the message has not yet started transmission, or if the message started but is interrupted by loss of arbitration or an error, the abort will be processed. The abort is indicated when the module sets the TXABT bit, and the TXxIF flag is not automatically set.

19.5.5 TRANSMISSION ERRORS

The CAN module will detect the following transmission errors:

- Acknowledge Error
- Form Error
- Bit Error

These transmission errors will not necessarily generate an interrupt but are indicated by the transmission error counter. However, each of these errors will cause the transmission error counter to be incremented by one. Once the value of the error counter exceeds the value of 96, the ERRIF (C1INTF<5>) and the TXWAR bit (C1INTF<10>) are set. Once the value of the error counter exceeds the value of 96, an interrupt is generated and the TXWAR bit in the error flag register is set.

TABLE 21-1: OSCILLATOR OPERATING MODES

Oscillator Mode	Description
XTL	200 kHz-4 MHz crystal on OSC1:OSC2
XT	4 MHz-10 MHz crystal on OSC1:OSC2
XT w/PLL 4x	4 MHz-10 MHz crystal on OSC1:OSC2, 4x PLL enabled
XT w/PLL 8x	4 MHz-10 MHz crystal on OSC1:OSC2, 8x PLL enabled
XT w/PLL 16x	4 MHz-10 MHz crystal on OSC1:OSC2, 16x PLL enabled(1)
LP	32 kHz crystal on SOSCO:SOSCI(2)
HS	10 MHz-25 MHz crystal
EC	External clock input (0-40 MHz)
ECIO	External clock input (0-40 MHz), OSC2 pin is I/O
EC w/PLL 4x	External clock input (0-40 MHz), OSC2 pin is I/O, 4x PLL enabled(1)
EC w/PLL 8x	External clock input (0-40 MHz), OSC2 pin is I/O, 8x PLL enabled(1)
EC w/PLL 16x	External clock input (0-40 MHz), OSC2 pin is I/O, 16x PLL enabled(1)
ERC	External RC oscillator, OSC2 pin is FOSC/4 output(3)
ERCIO	External RC oscillator, OSC2 pin is I/O(3)
FRC	8 MHz internal RC oscillator
FRC w/PLL 4x	7.37 MHz Internal RC oscillator, 4x PLL enabled
FRC w/PLL 8x	7.37 MHz Internal RC oscillator, 8x PLL enabled
FRC w/PLL 16x	7.37 MHz Internal RC oscillator, 16x PLL enabled
LPRC	512 kHz internal RC oscillator

Note 1: The dsPIC30F maximum operating frequency of 120 MHz must be met.
2: LP oscillator can be conveniently shared as a system clock, as well as a Real-Time Clock for Timer1.
3: Requires external R and C. Frequency operation up to 4 MHz.

AC CHARACTERISTICS				Standard Operating Conditions: 2.5V to 5.5V (unless otherwise stated) Operating temperature -40°C ≤ T_A ≤ +85°C for Industrial -40°C ≤ T_A ≤ +125°C for Extended			
Param No.	**Symbol**	**Characteristic[1]**		**Min**	**Max**	**Units**	**Conditions**
IC10	TccL	ICx Input Low Time	No prescaler	0.5 T_{CY} + 20	—	ns	
			With prescaler	10	—	ns	
IC11	TccH	ICx Input High Time	No prescaler	0.5 T_{CY} + 20	—	ns	
			With prescaler	10	—	ns	
IC15	TccP	ICx Input Period		(2 T_{CY} + 40)/N	—	ns	N = prescale value (1, 4, 16)

Note 1: These parameters are characterized but not tested in manufacturing.

TABLE 24-40: 10-BIT HIGH-SPEED A/D CONVERSION TIMING REQUIREMENTS

AC CHARACTERISTICS			Standard Operating Conditions: 2.5V to 5.5V (unless otherwise stated) Operating temperature -40°C ≤ T_A ≤ +85°C for Industrial -40°C ≤ T_A ≤ +125°C for Extended				
Param No.	**Symbol**	**Characteristic**	**Min.**	**Typ**	**Max.**	**Units**	**Conditions**
Clock Parameters							
AD50	T_{AD}	A/D Clock Period	—	84	—	ns	See Table 20-2(1)
AD51	t_{RC}	A/D Internal RC Oscillator Period	700	900	1100	ns	
Conversion Rate							
AD55	t_{CONV}	Conversion Time	—	12 T_{AD}	—	—	
AD56	F_{CNV}	Throughput Rate	—	1.0	—	Msps	See Table 20-2(1)
AD57	T_{SAMP}	Sample Time	—	1 T_{AD}	—	—	See Table 20-2(1)
Timing Parameters							
AD60	t_{PCS}	Conversion Start from Sample Trigger	—	1.0 T_{AD}	—	—	
AD61	t_{PSS}	Sample Start from Setting Sample (SAMP) Bit	0.5 T_{AD}	—	1.5 T_{AD}	—	
AD62	t_{CSS}	Conversion Completion to Sample Start (ASAM = 1)	—	0.5 T_{AD}	—	—	
AD63	t_{DPU}(2)	Time to Stabilize Analog Stage from A/D Off to A/D On	—	—	20	µs	

Note 1: Because the sample caps will eventually lose charge, clock rates below 10 kHz can affect linearity performance, especially at elevated temperatures.

2: t_{DPU} is the time required for the ADC module to stabilize when it is turned on (ADCON1<ADON> = 1). During this time the ADC result is indeterminate.
