

Welcome to [E-XFL.COM](#)

[Embedded - Microcontrollers - Application Specific](#): Tailored Solutions for Precision and Performance

[Embedded - Microcontrollers - Application Specific](#) represents a category of microcontrollers designed with unique features and capabilities tailored to specific application needs. Unlike general-purpose microcontrollers, application-specific microcontrollers are optimized for particular tasks, offering enhanced performance, efficiency, and functionality to meet the demands of specialized applications.

What Are [Embedded - Microcontrollers - Application Specific](#)?

Application specific microcontrollers are engineered to

Details

Product Status	Obsolete
Applications	USB Microcontroller
Core Processor	M8B
Program Memory Type	OTP (8kB)
Controller Series	CY7C634xx
RAM Size	256 x 8
Interface	PS/2, USB
Number of I/O	32
Voltage - Supply	4V ~ 5.5V
Operating Temperature	0°C ~ 70°C
Mounting Type	Surface Mount
Package / Case	48-BSSOP (0.295", 7.50mm Width)
Supplier Device Package	48-SSOP
Purchase URL	https://www.e-xfl.com/product-detail/infineon-technologies/cy7c63413-pvc

4.0 Programming Model

4.1 14-bit Program Counter (PC)

The 14-bit program counter (PC) allows access for up to 8 kilobytes of EPROM using the CY7C634/5xx architecture. The program counter is cleared during reset, such that the first instruction executed after a reset is at address 0x0000h. This is typically a jump instruction to a reset handler that initializes the application.

The lower 8 bits of the program counter are incremented as instructions are loaded and executed. The upper 6 bits of the program counter are incremented by executing an XPAGE instruction. As a result, the last instruction executed within a 256 byte “page” of sequential code should be an XPAGE instruction. The assembler directive “XPAGEON” will cause the assembler to insert XPAGE instructions automatically. As instructions can be either one or two bytes long, the assembler may occasionally need to insert a NOP followed by an XPAGE for correct execution.

The program counter of the next instruction to be executed, carry flag, and zero flag are saved as two bytes on the program stack during an interrupt acknowledge or a CALL instruction. The program counter, carry flag, and zero flag are restored from the program stack only during a RETI instruction.

Please note the program counter cannot be accessed directly by the firmware. The program stack can be examined by reading SRAM from location 0x00 and up.

4.2 8-bit Accumulator (A)

The accumulator is the general purpose, do everything register in the architecture where results are usually calculated.

4.3 8-bit Index Register (X)

The index register “X” is available to the firmware as an auxiliary accumulator. The X register also allows the processor to perform indexed operations by loading an index value into X.

4.4 8-bit Program Stack Pointer (PSP)

During a reset, the program stack pointer (PSP) is set to zero. This means the program “stack” starts at RAM address 0x00 and “grows” upward from there. Note the program stack pointer is directly addressable under firmware control, using the MOV PSP,A instruction. The PSP supports interrupt service under hardware control and CALL, RET, and RETI instructions under firmware control.

Figure 6-1. Program Memory Space with Interrupt Vector Table

6.2 Data Memory Organization

The CY7C63411/12/13 and CY7C63511/12/13 microcontrollers provide 256 bytes of data RAM. In normal usage, the SRAM is partitioned into four areas: program stack, data stack, user variables and USB endpoint FIFOs as shown below:

6.3 I/O Register Summary

I/O registers are accessed via the I/O Read (IORD) and I/O Write (IOWR, IOWX) instructions. IORD reads the selected port into the accumulator. IOWR writes data from the accumulator to the selected port. Indexed I/O Write (IOWX) adds the contents of X to the address in the instruction to form the port address and writes data from the accumulator to the specified port. Note that specifying address 0 (e.g., IOWX 0h) means the I/O port is selected solely by the contents of X.

Table 6-1. I/O Register Summary

Register Name	I/O Address	Read/Write	Function
Port 0 Data	0x00	R/W	GPIO Port 0
Port 1 Data	0x01	R/W	GPIO Port 1
Port 2 Data	0x02	R/W	GPIO Port 2
Port 3 Data	0x03	R/W	GPIO Port 3
Port 0 Interrupt Enable	0x04	W	Interrupt enable for pins in Port 0
Port 1 Interrupt Enable	0x05	W	Interrupt enable for pins in Port 1
Port 2 Interrupt Enable	0x06	W	Interrupt enable for pins in Port 2
Port 3 Interrupt Enable	0x07	W	Interrupt enable for pins in Port 3
GPIO Configuration	0x08	R/W	GPIO Ports Configurations
USB Device Address A	0x10	R/W	USB Device Address A
EP A0 Counter Register	0x11	R/W	USB Address A, Endpoint 0 counter register
EP A0 Mode Register	0x12	R/W	USB Address A, Endpoint 0 configuration register
EP A1 Counter Register	0x13	R/W	USB Address A, Endpoint 1 counter register
EP A1 Mode Register	0x14	R/C	USB Address A, Endpoint 1 configuration register
EP A2 Counter Register	0x15	R/W	USB address A, Endpoint 2 counter register
EP A2 Mode Register	0x16	R/C	USB address A, Endpoint 2 configuration register
USB Status & Control	0x1F	R/W	USB up-stream port traffic status and control register
Global Interrupt Enable	0x20	R/W	Global interrupt enable register
Endpoint Interrupt Enable	0x21	R/W	USB endpoint interrupt enables
Timer (LSB)	0x24	R	Lower 8 bits of free-running timer (1 MHz)
Timer (MSB)	0x25	R	Upper 4 bits of free-running timer that are latched when the lower 8 bits are read.
WDR Clear	0x26	W	Watch Dog Reset clear
DAC Data	0x30	R/W	DAC I/O
DAC Interrupt Enable	0x31	W	Interrupt enable for each DAC pin.
DAC Interrupt Polarity	0x32	W	Interrupt polarity for each DAC pin
DAC Isink	0x38-0x3F	W	One four bit sink current register for each DAC pin.
Processor Status & Control	0xFF	R/W	Microprocessor status and control

7.0 Clocking

Figure 7-1. Clock Oscillator On-chip Circuit

The XTAL_{IN} and XTAL_{OUT} are the clock pins to the microcontroller. The user can connect a low-cost ceramic resonator or an external oscillator can be connected to these pins to provide a reference frequency for the internal clock distribution and clock doubler.

An external 6 MHz clock can be applied to the XTAL_{IN} pin if the XTAL_{OUT} pin is left open. Please note that grounding the XTAL_{OUT} pin is not permissible as the internal clock is effectively shorted to ground.

8.0 Reset

The USB Controller supports three types of resets. All registers are restored to their default states during a reset. The USB Device Addresses are set to 0 and all interrupts are disabled. In addition, the Program Stack Pointer (PSP) and Data Stack Pointer (DSP) are set to 0x00. For USB applications, the firmware should set the DSP below 0xE8h to avoid a memory conflict with RAM dedicated to USB FIFOs. The assembly instructions to do this are shown below:

```
Mov A, E8h    ; Move 0xE8 hex into Accumulator
Swap A,dsp    ; swap accumulator value into dsp register
```

The three reset types are:

1. Power-On Reset (POR)
2. Watch Dog Reset (WDR)
3. USB Bus Reset (non hardware reset)

The occurrence of a reset is recorded in the Processor Status and Control Register located at I/O address 0xFF. Bits 4, 5, and 6 are used to record the occurrence of POR, USB Reset, and WDR respectively. The firmware can interrogate these bits to determine the cause of a reset.

The microcontroller begins execution from ROM address 0x0000h after a POR or WDR reset. Although this looks like interrupt vector 0, there is an important difference. Reset processing does NOT push the program counter, carry flag, and zero flag onto program stack. That means the reset handler in firmware should initialize the hardware and begin executing the “main” loop of code. Attempting to execute either a RET or RETI in the reset handler will cause unpredictable execution results.

8.1 Power-On Reset (POR)

Power-On Reset (POR) occurs every time the V_{CC} voltage to the device ramps from 0V to an internally defined trip voltage (V_{rst}), of approximately 1/2 full supply voltage. In addition to the normal reset initialization noted under “Reset,” bit 4 (PORS) of the Processor Status and Control Register is set to “1” to indicate to the firmware that a power on reset occurred. The POR event forces the GPIO ports into input mode (high impedance), and the state of Port 3 bit 7 is used to control how the part will respond after the POR releases.

If Port 3 bit 7 is high (pulled to V_{CC}) and the USB IO are at the idle state (DM high and DP low) the part will go into a semi-permanent power down/suspend mode, waiting for the USB IO to go to one of Bus Reset, K (resume) or SE0. If Port 3 bit 7 is still high when the part comes out of suspend, then a 128 us timer starts, delaying CPU operation until the ceramic resonator has stabilized.

If Port 3 bit 7 was low (pulled to V_{SS}) the part will start a 128 ms timer, delaying CPU operation until V_{CC} has stabilized, then continuing to run as reset.

Firmware should clear the POR Status (PORS) bit in register FFh before going into suspend as this status bit selects the 128 μs or 128 ms start-up timer value as follows: IF Port 3 bit 7 is high then 128 μs is always used; ELSE if PORS is high then 128 ms is used; ELSE 128 μs is used.

provides “HIGH” source current when the GPIO port is configured for CMOS outputs and the output data bit is written as a “1”. Q2 and Q3 are sized to sink and source, respectively, roughly the same amount of current to support traditional CMOS outputs with symmetric drive.

-------	-------	-------	-------	-------	-------	-------	-------

Figure 9-5. Port 3 Data 0x03h (read/write)

Port 3 has eight GPIO pins. Port 3 (8 bits) can be configured as inputs with internal pull-ups, open drain outputs, or traditional CMOS outputs. An open drain output is also a high-impedance input. Port 3 offers high current drive with a typical current sink capability of 12 mA. The internal pull-up resistors are typically 7 Kohms.

During reset, all of the GPIO pins are set to output “1” (input) with the internal pull-up enabled. In this state, a “1” will always be read on that GPIO pin unless an external current sink drives the output to a “0” state. Writing a “0” to a GPIO pin enables the output current sink to ground (LOW) and disables the internal pull-up for that pin.

9.1 GPIO Interrupt Enable Ports

During a reset, GPIO interrupts are disabled by clearing all of the GPIO interrupt enable ports. Writing a “1” to a GPIO Interrupt Enable bit enables GPIO interrupts from the corresponding input pin.

9.2 GPIO Configuration Port

Every GPIO port can be programmed as inputs with internal pull-ups, open drain outputs, and traditional CMOS outputs. In addition, the interrupt polarity for each port can be programmed. With positive interrupt polarity, a rising edge (“0” to “1”) on an input pin causes an interrupt. With negative polarity, a falling edge (“1” to “0”) on an input pin causes an interrupt. As shown in the table below, when a GPIO port is configured with CMOS outputs, interrupts from that port are disabled. The GPIO Configuration Port register provides two bits per port to program these features. The possible port configurations are:

Port Configuration bits	Pin Interrupt Bit	Driver Mode	Interrupt Polarity
11	X	Resistive	-
10	0	CMOS Output	disabled
10	1	CMOS Input	disabled
01	X	Open Drain	-
00	X	Open Drain	+ (default)

In “Resistive” mode, a 7 Kohm pull-up resistor is conditionally enabled for all pins of a GPIO port. The resistor is enabled for any pin that has been written as a “1.” The resistor is disabled on any pin that has been written as a “0”. An I/O pin will be driven high through a 7 Kohm pull-up resistor when a “1” has been written to the pin. Or the output pin will be driven LOW, with the pull-up disabled, when a “0” has been written to the pin. An I/O pin that has been written as a “1” can be used as an input pin with an integrated 7 Kohm pull-up resistor. Resistive mode selects a negative (falling edge) interrupt polarity on all pins that have the GPIO interrupt enabled.

A port configured in CMOS mode has interrupt generation disabled, yet the interrupt mask bits serve to control port direction. If a port’s associated Interrupt Mask bits are cleared, those port bits are strictly outputs. If the Interrupt Mask bits are set then those bits will be open drain inputs. As open drain inputs, if their data output values are ‘1’ those port pins will be CMOS inputs (HIGH Z output).

In “Open Drain” mode the internal pull-up resistor and CMOS driver (HIGH) are both disabled. An I/O pin that has been written as a “1” can be used as either a high-impedance input or a three-state output. An I/O pin that has been written as a “0” will drive the output LOW. The interrupt polarity for an open drain GPIO port can be selected as either positive (rising edge) or negative (falling edge).

During reset, all of the bits in the GPIO Configuration Register are written with “0”. This selects the default configuration: Open Drain output, positive interrupt polarity for all GPIO ports.

11.1 USB Enumeration

The enumeration sequence is shown below:

1. The host computer sends a **Setup** packet followed by a **Data** packet to USB address 0 requesting the Device descriptor.
2. The USB Controller decodes the request and retrieves its Device descriptor from the program memory space.
3. The host computer performs a control read sequence and the USB Controller responds by sending the Device descriptor over the USB bus.
4. After receiving the descriptor, the host computer sends a **Setup** packet followed by a **Data** packet to address 0 assigning a new USB address to the device.
5. The USB Controller stores the new address in its USB Device Address Register after the no-data control sequence completes.
6. The host sends a request for the Device descriptor using the new USB address.
7. The USB Controller decodes the request and retrieves the Device descriptor from the program memory.
8. The host performs a control read sequence and the USB Controller responds by sending its Device descriptor over the USB bus.
9. The host generates control reads to the USB Controller to request the Configuration and Report descriptors.
10. The USB Controller retrieves the descriptors from its program space and returns the data to the host over the USB.

11.2 PS/2 Operation

PS/2 operation is possible with the CY7C634/5xx series through the use of firmware and several operating modes. The first enabling feature:

1. USB Bus reset on D+ and D– is an interrupt that can be disabled;
2. USB traffic can be disabled via bit7 of the USB register;
3. D+ and D– can be monitored and driven via firmware as independent port bits.

Bits 5 and 4 of the Upstream Status and Control register are directly connected to the D+ and D– USB pins of the CY7C634/5xx. These pins constantly monitor the levels of these signals with CMOS input thresholds. Firmware can poll and decode these signals as PS/2 clock and data.

Bits [2:0] defaults to '000' at reset which allows the USB SIE to control output on D+ and D–. Firmware can override the SIE and directly control the state of these pins via these 3 control bits. Since PS/2 is an open drain signalling protocol, these modes allow all 4 PS/2 states to be generated on the D+ and D– pins

11.3 USB Port Status and Control

USB status and control is regulated by the USB Status and Control Register located at I/O address 0x1Fh as shown in *Figure 11-1*. This is a read/write register. All reserved bits must be written to zero. All bits in the register are cleared during reset.

7	6	5	4	3	2	1	0
		R	R	R/W	R/W	R/W	R/W
Reserved	Reserved	D+	D–	Bus Activity	Control Bit 2	Control Bit 1	Control Bit 0

Figure 11-1. USB Status and Control Register 0x1Fh

The Bus Activity bit is a “sticky” bit that indicates if any non-idle USB event has occurred on the USB bus. The user firmware should check and clear this bit periodically to detect any loss of bus activity. Writing a “0” to the Bus Activity bit clears it while writing a “1” preserves the current value. In other words, the firmware can clear the Bus Activity bit, but only the SIE can set it. The 1.024 ms timer interrupt service routine is normally used to check and clear the Bus Activity bit. The following table shows how the control bits are encoded for this register.

Control Bits	Control action
000	Not forcing (SIE controls driver)
001	Force K (D+ high, D– low)
010	Force J (D+ low, D– high)
011	Force SE0 (D+ low, D– low)
100	Force SE0 (D– low, D+ low)
101	Force D– low, D+ HiZ
110	Force D– HiZ, D+ low
111	Force D– HiZ, D+ HiZ

12.0 USB Device

USB Device Address A includes three endpoints: EPA0, EPA1, and EPA2. End Point 0 (EPA0) allows the USB host to recognize, set-up, and control the device. In particular, EPA0 is used to receive and transmit control (including set-up) packets.

12.1 USB Ports

The USB Controller provides one USB device address with three endpoints. The USB Device Address Register contents are cleared during a reset, setting the USB device address to zero and marking this address as disabled. *Figure 12-1* shows the format of the USB Address Register.

Device Address Enable	Device Address Bit 6	Device Address Bit 5	Device Address Bit 4	Device Address Bit 3	Device Address Bit 2	Device Address Bit 1	Device Address Bit 0
-----------------------	----------------------	----------------------	----------------------	----------------------	----------------------	----------------------	----------------------

Figure 12-1. USB Device Address Register 0x10h (read/write)

Bit 7 (Device Address Enable) in the USB Device Address Register must be set by firmware before the serial interface engine (SIE) will respond to USB traffic to this address. The Device Address in bits [6:0] must be set by firmware during the USB enumeration process to an address assigned by the USB host that does not equal zero. This register is cleared by a hardware reset or the USB bus reset.

12.2 Device Endpoints (3)

The USB controller communicates with the host using dedicated FIFOs, one per endpoint. Each endpoint FIFO is implemented as 8 bytes of dedicated SRAM. There are three endpoints defined for Device “A” that are labeled “EPA0,” “EPA1,” and EPA2.”

All USB devices are required to have an endpoint number 0 (EPA0) that is used to initialize and control the USB device. End Point 0 provides access to the device configuration information and allows generic USB status and control accesses. End Point 0 is bidirectional as the USB controller can both receive and transmit data.

The endpoint mode registers are cleared during reset. The EPA0 endpoint mode register uses the format shown below:

Endpoint 0 set-up Received	Endpoint 0 In Received	Endpoint 0 Out Received	Acknowledge	Mode Bit 3	Mode Bit 2	Mode Bit 1	Mode Bit 0
----------------------------	------------------------	-------------------------	-------------	------------	------------	------------	------------

Figure 12-2. USB Device EPA0 Mode Register 0x12h (read/write)

Bits[7:5] in the endpoint 0 mode registers (EPA0) are “sticky” status bits that are set by the SIE to report the type of token that was most recently received. The sticky bits must be cleared by firmware as part of the USB processing.

The endpoint mode registers for EPA1 and EPA2 do not use bits [7:5] as shown below:

Reserved	Reserved	Reserved	Acknowledge	Mode Bit 3	Mode Bit 2	Mode Bit 1	Mode Bit 0
----------	----------	----------	-------------	------------	------------	------------	------------

Figure 12-3. USB Device Endpoint Mode Registers 0x14h, 0x16h (read/write)

The ‘Acknowledge’ bit is set whenever the SIE engages in a transaction that completes with an ‘ACK’ packet.

The 'set-up' PID status (bit[7]) is forced high from the start of the data packet phase of the set-up transaction, until the start of the ACK packet returned by the SIE. The CPU is prevented from clearing this bit during this interval, and subsequently until the CPU first does a IORD to this endpoint 0 mode register.

Bits[6:0] of the endpoint 0 mode register are locked from CPU IOWR operations only if the SIE has updated one of these bits, which the SIE does only at the end of a packet transaction (set-up ... Data ... ACK, or Out ... Data ... ACK, or In ... Data ... ACK). The CPU can unlock these bits by doing a subsequent I/O read of this register.

Firmware must do an IORD after an IOWR to an endpoint 0 register to verify that the contents have changed and that the SIE has not updated these values.

While the 'set-up' bit is set, the CPU cannot write to the DMA buffers at memory locations 0xE0 through 0xE7 and 0xF8 through 0xFF. This prevents an incoming set-up transaction from conflicting with a previous In data buffer filling operation by firmware.

The mode bits (bits [3:0]) in an Endpoint Mode Register control how the endpoint responds to USB bus traffic. The mode bit encoding is shown in Section 16.

The format of the endpoint Device counter registers is shown below:

Data 0/1 Toggle	Data Valid	Reserved	Reserved	Byte count Bit 3	Byte count Bit 2	Byte count Bit 1	Byte count Bit 0
-----------------	------------	----------	----------	------------------	------------------	------------------	------------------

Figure 12-4. USB Device Counter Registers 0x11h, 0x13h, 0x15h (read/write)

Bits 0 to 3 indicate the number of data bytes to be transmitted during an IN packet, valid values are 0 to 8 inclusive. Data Valid bit 6 is used for OUT and set-up tokens only. Data 0/1 Toggle bit 7 selects the DATA packet's toggle state: 0 for DATA0, 1 for DATA1.

13.0 12-bit Free-running Timer

The 12-bit timer provides two interrupts (128 μ s and 1.024 ms) and allows the firmware to directly time events that are up to 4 ms in duration. The lower 8 bits of the timer can be read directly by the firmware. Reading the lower 8 bits latches the upper 4 bits into a temporary register. When the firmware reads the upper 4 bits of the timer, it is actually reading the count stored in the temporary register. The effect of this logic is to ensure a stable 12-bit timer value can be read, even when the two reads are separated in time.

13.1 Timer (LSB)

Timer Bit 7	Timer Bit 6	Timer Bit 5	Timer Bit 4	Timer Bit 3	Timer Bit 2	Timer Bit 1	Timer Bit 0
-------------	-------------	-------------	-------------	-------------	-------------	-------------	-------------

14.0 Processor Status and Control Register

7	6	5	4	3	2	1	0
R	R/W	R/W	R/W	R/W	R	R/W	R/W
IRQ pending	Watch Dog Reset	USB Bus Reset	Power-on Reset	Suspend, wait for interrupt	Interrupt Mask	Single Step	Run

Figure 14-1. Processor Status and Control Register 0xFFh

The “run” (bit 0) is manipulated by the HALT instruction. When Halt is executed, the processor clears the run bit and halts at the end of the current instruction. The processor remains halted until a reset (power on or watchdog). Notice, when writing to the processor status and control register, the run bit should always be written as a “1”.

The “single step” (bit 1) is provided to support a hardware debugger. When single step is set, the processor will execute one instruction and halt (clear the run bit). This bit must be cleared for normal operation.

The “Interrupt Mask” (bit 2) shows whether interrupts are enabled or disabled. The firmware has no direct control over this bit as writing a zero or one to this bit position will have no effect on interrupts. Instructions DI, EI, and RETI manipulate the internal hardware that controls the state of the interrupt mask bit in the Processor Status and Control Register.

Writing a “1” to “Suspend, wait for interrupts” (bit 3) will halt the processor and cause the microcontroller to enter the “suspend” mode that significantly reduces power consumption. A pending interrupt or bus activity will cause the device to come out of suspend. After coming out of suspend, the device will resume firmware execution at the instruction following the IOWR which put the part into suspend. An IOWR that attempts to put the part into suspend will be ignored if either bus activity or an interrupt is pending.

The “Power-on Reset” (bit 4) is only set to “1” during a power on reset. The firmware can check bits 4 and 6 in the reset handler to determine whether a reset was caused by a power on condition or a watchdog timeout. PORS is used to determine suspend start-up timer value of 128us or 128ms.

The “USB Bus Reset” (bit 5) will occur when a USB bus reset is received. The USB Bus Reset is a singled-ended zero (SE0) that lasts more than 8 microseconds. An SE0 is defined as the condition in which both the D+ line and the D– line are LOW at the same time. When the SIE detects this condition, the USB Bus Reset bit is set in the Processor Status and Control register and an USB Bus Reset interrupt is generated. Please note this is an interrupt to the microcontroller and does not actually reset the processor.

The “Watch Dog Reset” (bit 6) is set during a reset initiated by the watchdog timer. This indicates the watchdog timer went for more than 8 ms between watch dog clears.

The “IRQ pending” (bit 7) indicates one or more of the interrupts has been recognized as active. The interrupt acknowledge sequence should clear this bit until the next interrupt is detected.

During power on reset, the Processor Status and Control Register is set to 00010001, which indicates a power-on-reset (bit 4 set) has occurred and no interrupts are pending (bit 7 clear), yet.

During a watchdog reset, the Processor Status and Control Register is set to 01000001, which indicates a watchdog reset (bit 6 set) has occurred and no interrupts are pending (bit 7 clear), yet.

15.0 Interrupts

All interrupts are maskable by the Global Interrupt Enable Register and the USB End Point Interrupt Enable Register. Writing a “1” to a bit position enables the interrupt associated with that bit position. During a reset, the contents the Global Interrupt Enable Register and USB End Point Interrupt Enable Register are cleared, effectively disabling all interrupts.

7	6	5	4	3	2	1	0
			R/W	R/W	R/W	R/W	R/W
Reserved	Reserved	GPIO Interrupt Enable	DAC Interrupt Enable	Reserved	1.024 ms Interrupt Enable	128 μ sec Interrupt Enable	USB Bus RST Interrupt Enable

Figure 15-1. Global Interrupt Enable Register 0x20h (read/write)

15.2.2 Timer Interrupt

There are two timer interrupts: the 128 μ s interrupt and the 1.024 ms interrupt. The user should disable both timer interrupts before going into the suspend mode to avoid possible conflicts between servicing the interrupts first or the suspend request first.

15.2.3 USB Endpoint Interrupts

There are three USB endpoint interrupts, one per endpoint. The USB endpoints interrupt after the either the USB host or the USB controller sends a packet to the USB.

15.2.4 DAC Interrupt

Each DAC I/O pin can generate an interrupt, if enabled. The interrupt polarity for each DAC I/O pin is programmable. A positive polarity is a rising edge input while a negative polarity is a falling edge input. All of the DAC pins share a single interrupt vector, which means the firmware will need to read the DAC port to determine which pin or pins caused an interrupt.

Please note that if one DAC pin triggered an interrupt, no other DAC pins can cause a DAC interrupt until that pin has returned to its inactive (non-trigger) state or the corresponding interrupt enable bit is cleared. The USB Controller does not assign interrupt priority to different DAC pins and the DAC Interrupt Enable Register is not cleared during the interrupt acknowledge process.

15.2.5 GPIO Interrupt

Each of the 32 GPIO pins can generate an interrupt, if enabled. The interrupt polarity can be programmed for each GPIO port as part of the GPIO configuration. All of the GPIO pins share a single interrupt vector, which means the firmware will need to read the GPIO ports with enabled interrupts to determine which pin or pins caused an interrupt.

Please note that if one port pin triggered an interrupt, no other port pins can cause a GPIO interrupt until that port pin has returned to its inactive (non-trigger) state or its corresponding port interrupt enable bit is cleared. The USB Controller does not assign interrupt priority to different port pins and the Port Interrupt Enable Registers are not cleared during the interrupt acknowledge process.

16.0 Truth Tables

Table 16-1. USB Register Mode Encoding

Mode	Encoding	Setup	In	Out	Comments
Disable	0000	ignore	ignore	ignore	Ignore all USB traffic to this endpoint
Nak In/Out	0001	accept	NAK	NAK	"Forced from Setup on Control endpoint, from modes other than 0000"
Status Out Only	0010	accept	stall	check	For Control endpoints
Stall In/Out	0011	accept	stall	stall	For Control endpoints
Ignore In/Out	0100	accept	ignore	ignore	For Control endpoints
Isochronous Out	0101	ignore	ignore	always	"(available to low speed devices, future USB spec enhancements)" In Only
Status In Only	0110	accept	TX 0	stall	For Control Endpoints
Isochronous In	0111	ignore	TX cnt	ignore	"(available to low speed devices, future USB spec enhancements)"
Nak Out	1000	ignore	ignore	NAK	An ACK from mode 1001 --> 1000
Ack Out	1001	ignore	ignore	ACK	This mode is changed by SIE on issuance of ACK --> 1000
Nak Out - Status In	1010	accept	TX 0	NAK	An ACK from mode 1011 --> 1010
Ack Out - Status In	1011	accept	TX 0	ACK	This mode is changed by SIE on issuance of ACK --> 1010
Nak In	1100	ignore	NAK	ignore	An ACK from mode 1101 --> 1100
Ack In	1101	ignore	TX cnt	ignore	This mode is changed by SIE on issuance of ACK --> 1100
Nak In - Status Out	1110	accept	NAK	check	An ACK from mode 1111 --> 111 Ack In - Status Out
Ack In - Status Out	1111	accept	TX cnt	Check	This mode is changed by SIE on issuance of ACK --> 1110

The 'In' column represents the SIE's response to the token type.

A disabled endpoint will remain such until firmware changes it, and all endpoints reset to disabled.

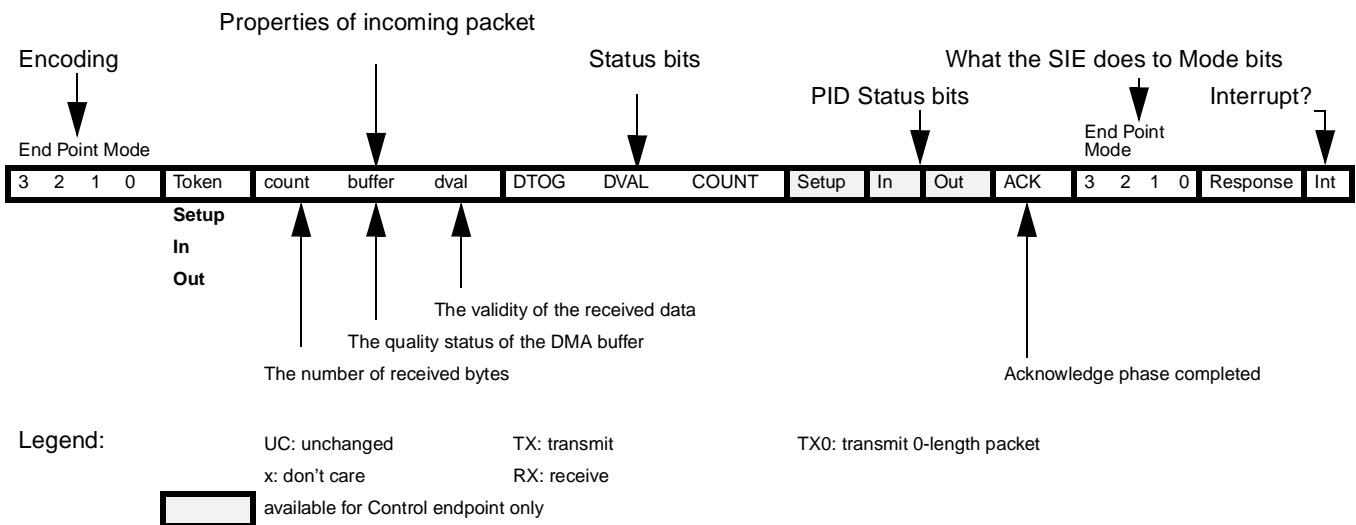

Any Setup packet to an enabled and accepting endpoint will be changed by the SIE to 0001 (NAKing). Any mode which indicates the acceptance of a Setup will acknowledge it.

Most modes that control transactions involving an ending ACK will be changed by the SIE to a corresponding mode which NAKs follow on packets.

A Control endpoint has three extra status bits for PID (Setup, In and Out), but must be placed in the correct mode to function as such. Also a non-Control endpoint can be made to act as a Control endpoint if it is placed in a non appropriate mode!

A 'check' on an Out token during a Status transaction checks to see that the Out is of zero length and has a Data Toggle (DTOG) of 1.

Table 16-2. Decode table for Table 16-3: "Details of Modes for Differing Traffic Conditions"

The response of the SIE can be summarized as follows:

- (1) the SIE will only respond to valid transactions, and will ignore non-valid ones;
- (2) the SIE will generate IRQ when a valid transaction is completed or when the DMA buffer is corrupted;
- (3) an incoming Data packet is valid if the count is ≤ 10 (CRC inclusive) and passes all error checking;
- (4) a Setup will be ignored by all non Control endpoints (in appropriate modes);
- (5) an In will be ignored by an Out configured endpoint and visa versa.

The In and Out PID status is updated at the end of a transaction.

The Setup PID status is updated at the beginning of the Data packet phase.

The entire EndPoint 0 mode and the Count register are locked to CPU writes at the end of any transaction in which an ACK is transferred. These registers are only unlocked upon a CPU read of these registers, and only if that read happens after the transaction completes. This represents about a 1 μ s window to which to the CPU is locked from register writes to these USB registers. Normally the firmware does a register read at the beginning of the ISR to unlock and get the mode register information. The interlock on the Mode and Count registers ensures that the firmware recognizes the changes that the SIE might have made during the previous transaction!
