Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Obsolete
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	36864
Number of I/O	68
Number of Gates	250000
Voltage - Supply	1.14V ~ 1.575V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 85°C (TJ)
Package / Case	100-TQFP
Supplier Device Package	100-VQFP (14x14)
Purchase URL	https://www.e-xfl.com/product-detail/microsemi/a3p250l-1vqg100

Table 1-4 • IGLOO nano and ProASIC3 nano Array Coordinates

Device		VersaTiles		Memory Rows		Entire Die	
		Min.	Max.	Bottom	Top	Min.	Max.
IGLOO nano	ProASIC3 nano	(x, y)	(x, y)	(x, y)	(x, y)	(x, y)	(x, y)
AGLN010	A3P010	(0, 2)	(32, 5)	None	None	(0, 0)	(34, 5)
AGLN015	A3PN015	(0, 2)	(32, 9)	None	None	(0, 0)	(34, 9)
AGLN020	A3PN020	(0, 2)	32, 13)	None	None	(0, 0)	(34, 13)
AGLN060	A3PN060	(3, 2)	(66, 25)	None	(3, 26)	(0, 0)	(69, 29)
AGLN125	A3PN125	(3, 2)	(130, 25)	None	(3, 26)	(0, 0)	(133, 29)
AGLN250	A3PN250	(3, 2)	(130, 49)	None	(3, 50)	(0, 0)	(133, 49)

Note: The vertical I/O tile coordinates are not shown. West-side coordinates are {(0, 2) to (2, 2)} to {(0, 77) to (2, 77)}; east-side coordinates are {(195, 2) to (197, 2)} to {(195, 77) to (197, 77)}.

Figure 1-9 • Array Coordinates for AGL600, AGL600, A3P600, and A3PE600

Figure 3-6 shows all nine global inputs for the location A connected to the top left quadrant global network via CCC.

Figure 3-6 • Global Inputs

Since each bank can have a different I/O standard, the user should be careful to choose the correct global I/O for the design. There are 54 global pins available to access 18 global networks. For the single-ended and voltage-referenced I/O standards, you can use any of these three available I/Os to access the global network. For differential I/O standards such as LVDS and LVPECL, the I/O macro needs to be placed on (A0, A1), (B0, B1), (C0, C1), or a similar location. The unassigned global I/Os can be used as regular I/Os. Note that pin names starting with GF and GC are associated with the chip global networks, and GA, GB, GD, and GE are used for quadrant global networks. Table 3-2 on page 54 and Table 3-3 on page 55 show the general chip and quadrant global pin names.

Simple Design Example

Consider a design consisting of six building blocks (shift registers) and targeted for an A3PE600-PQ208 (Figure 3-16 on page 68). The example design consists of two PLLs (PLL1 has GLA only; PLL2 has both GLA and GLB), a global reset (ACLR), an enable (EN_ALL), and three external clock domains (QCLK1, QCLK2, and QCLK3) driving the different blocks of the design. Note that the PQ208 package only has two PLLs (which access the chip global network). Because of fanout, the global reset and enable signals need to be assigned to the chip global resources. There is only one free chip global for the remaining global (QCLK1, QCLK2, QCLK3). Place two of these signals on the quadrant global resource. The design example demonstrates manually assignment of QCLK1 and QCLK2 to the quadrant global using the PDC command.

Figure 3-19 • Block Diagram of the Global Management Example Design

Primary Clock Output Delay from CLKA -3.020

Secondary1 Clock frequency 40.000

Secondary1 Clock Phase Shift 0.000

Secondary1 Clock Global Output Delay from CLKA 2.515

Next, perform simulation in ModelSim to verify the correct delays. Figure 4-30 shows the simulation results. The delay values match those reported in the SmartGen PLL Wizard.

Figure 4-30 • ModelSim Simulation Results

The timing can also be analyzed using SmartTime in Designer. The user should import the synthesized netlist to Designer, perform Compile and Layout, and then invoke SmartTime. Go to **Tools > Options** and change the maximum delay operating conditions to **Typical Case**. Then expand the Clock-to-Out paths of GLA and GLB and the individual components of the path delays are shown. The path of GLA is shown in Figure 4-31 on page 123 displaying the same delay value.

Simulation of FlashROM Design

The MEM file has 128 rows of 8 bits, each representing the contents of the FlashROM used for simulation. For example, the first row represents page 0, byte 0; the next row is page 0, byte 1; and so the pattern continues. Note that the three MSBs of the address define the page number, and the four LSBs define the byte number. So, if you send address 0000100 to FlashROM, this corresponds to the page 0 and byte 4 location, which is the fifth row in the MEM file. SmartGen defaults to 0s for any unspecified location of the FlashROM. Besides using the MEM file generated by SmartGen, you can create a binary file with 128 rows of 8 bits each and use this as a MEM file. Microsemi recommends that you use different file names if you plan to generate multiple MEM files. During simulation, Libero SoC passes the MEM file used as the generic file in the netlist, along with the design files and testbench. If you want to use different MEM files during simulation, you need to modify the generic file reference in the netlist.

```
.....
UFROM0: UFROM
--generic map(MEMORYFILE => "F:\Appsnotes\FROM\test_designs\testa\smartgen\FROM_a.mem")
--generic map(MEMORYFILE => "F:\Appsnotes\FROM\test_designs\testa\smartgen\FROM_b.mem")
.....
```

The VITAL and Verilog simulation models accept the generics passed by the netlist, read the MEM file, and perform simulation with the data in the file.

Programming File Generation for FlashROM Design

FlashPoint is the programming software used to generate the programming files for flash devices. Depending on the applications, you can use the FlashPoint software to generate a STAPL file with different FlashROM contents. In each case, optional AES decryption is available. To generate a STAPL file that contains the same FPGA core content and different FlashROM contents, the FlashPoint software needs an Array Map file for the core and UFC file(s) for the FlashROM. This final STAPL file represents the combination of the logic of the FPGA core and FlashROM content.

FlashPoint generates the STAPL files you can use to program the desired FlashROM page and/or FPGA core of the FPGA device contents. FlashPoint supports the encryption of the FlashROM content and/or FPGA Array configuration data. In the case of using the FlashROM for device serialization, a sequence of unique FlashROM contents will be generated. When generating a programming file with multiple unique FlashROM contents, you can specify in FlashPoint whether to include all FlashROM content in a single STAPL file or generate a different STAPL file for each FlashROM (Figure 5-11). The programming software (FlashPro) handles the single STAPL file that contains the FlashROM content from multiple devices. It enables you to program the FlashROM content into a series of devices sequentially (Figure 5-11). See the *FlashPro User's Guide* for information on serial programming.

Figure 5-11 • Single or Multiple Programming File Generation

Table 6-2 • Allowable Aspect Ratio Settings for WIDTHA[1:0]

WIDTHA[1:0]	WIDTHB[1:0]	D×W
00	00	4k×1
01	01	2k×2
10	10	1k×4
11	11	512×9

Note: The aspect ratio settings are constant and cannot be changed on the fly.

BLKA and BLKB

These signals are active-low and will enable the respective ports when asserted. When a BLKx signal is deasserted, that port's outputs hold the previous value.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, BLKB should be tied to ground.

WENA and WENB

These signals switch the RAM between read and write modes for the respective ports. A LOW on these signals indicates a write operation, and a HIGH indicates a read.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, WENB should be tied to ground.

CLKA and CLKB

These are the clock signals for the synchronous read and write operations. These can be driven independently or with the same driver.

Note: For Automotive ProASIC3 devices, dual-port mode is supported if the clocks to the two SRAM ports are the same and 180° out of phase (i.e., the port A clock is the inverse of the port B clock). For use of this macro as a single-port SRAM, the inputs and clock of one port should be tied off (grounded) to prevent errors during design compile.

PIPEA and PIPEB

These signals are used to specify pipelined read on the output. A LOW on PIPEA or PIPEB indicates a nonpipelined read, and the data appears on the corresponding output in the same clock cycle. A HIGH indicates a pipelined read, and data appears on the corresponding output in the next clock cycle.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, PIPEB should be tied to ground. For use in dual-port mode, the same clock with an inversion between the two clock pins of the macro should be used in the design to prevent errors during compile.

WMODEA and WMODEB

These signals are used to configure the behavior of the output when the RAM is in write mode. A LOW on these signals makes the output retain data from the previous read. A HIGH indicates pass-through behavior, wherein the data being written will appear immediately on the output. This signal is overridden when the RAM is being read.

Note: When using the SRAM in single-port mode for Automotive ProASIC3 devices, WMODEB should be tied to ground.

RESET

This active-low signal resets the control logic, forces the output hold state registers to zero, disables reads and writes from the SRAM block, and clears the data hold registers when asserted. It does not reset the contents of the memory array.

While the RESET signal is active, read and write operations are disabled. As with any asynchronous reset signal, care must be taken not to assert it too close to the edges of active read and write clocks.

ADDRA and ADDRb

These are used as read or write addresses, and they are 12 bits wide. When a depth of less than 4 k is specified, the unused high-order bits must be grounded (Table 6-3 on page 155).

Figure 7-17 • Timing Diagram (bypasses skew circuit)

Figure 7-18 • Timing Diagram (with skew circuit selected)

Note: The 30 k gate devices do not support a PLL (V_{COMPLF} and V_{CCPLF} pins).

List of Changes

The following table lists critical changes that were made in each revision of the document.

Date	Change	Page
August 2012	Figure 7-1 • DDR Configured I/O Block Logical Representation and Figure 7-2 • DDR Configured I/O Block Logical Representation were revised to indicate that resets on registers 1, 3, 4, and 5 are active high rather than active low. The title of the figures was revised from "I/O Block Logical Representation" (SAR 38215).	175, 181
	AGL015 and A3P015 were added to Table 7-2 • Supported I/O Standards. 1.2 V was added under single-ended I/O standards. LVCMOS 1.2 was added to Table 7-3 • VCCI Voltages and Compatible IGLOO and ProASIC3 Standards (SAR 38096).	177
	Figure 7-4 • Simplified I/O Buffer Circuitry and Table 7-7 • Programmable I/O Features (user control via I/O Attribute Editor) were modified to indicate that programmable input delay control is applicable only to ProASIC3EL and RT ProASIC3 devices (SAR 39666).	183, 188
	The following sentence is incorrect and was removed from the "LVCMOS (Low-Voltage CMOS)" section (SAR 40191): LVCMOS 2.5 V for the 30 k gate devices has a clamp diode to VCCI, but for all other devices there is no clamp diode.	184
	The hyperlink for the <i>Board-Level Considerations</i> application note was corrected (SAR 36663).	208, 210
June 2011	Figure 7-1 • DDR Configured I/O Block Logical Representation and Figure 7-2 • DDR Configured I/O Block Logical Representation were revised so that the I/O_CLR and I/O_OCLK nets are no longer joined in front of Input Register 3 but instead on the branch of the CLR/PRE signal (SAR 26052).	175, 181
	Table 7-1 • Flash-Based FPGAs was revised to remove RT ProASIC3 and add Military ProASIC3/EL in its place (SAR 31824, 31825).	176
	The "Advanced I/Os—IGLOO, ProASIC3L, and ProASIC3" section was revised. Formerly it stated, "3.3 V PCI and 3.3 V PCI-X are 5 V-tolerant." This sentence now reads, "3.3 V PCI and 3.3 V PCI-X can be configured to be 5 V-tolerant" (SAR 20983).	177

I/O Bank Structure

Low power flash device I/Os are divided into multiple technology banks. The number of banks is device-dependent. The IGLOOe, ProASIC3EL, and ProASIC3E devices have eight banks (two per side); and IGLOO, ProASIC3L, and ProASIC3 devices have two to four banks. Each bank has its own V_{CCI} power supply pin. Multiple I/O standards can co-exist within a single I/O bank.

In IGLOOe, ProASIC3EL, and ProASIC3E devices, each I/O bank is subdivided into V_{REF} minibanks. These are used by voltage-referenced I/Os. VREF minibanks contain 8 to 18 I/Os. All I/Os in a given minibank share a common VREF line (only one VREF pin is needed per VREF minibank). Therefore, if an I/O in a VREF minibank is configured as a VREF pin, the remaining I/Os in that minibank will be able to use the voltage assigned to that pin. If the location of the VREF pin is selected manually in the software, the user must satisfy VREF rules (refer to the "I/O Software Control in Low Power Flash Devices" section on page 251). If the user does not pick the VREF pin manually, the software automatically assigns it.

Figure 8-4 is a snapshot of a section of the I/O ring, showing the basic elements of an I/O tile, as viewed from the Designer place-and-route tool's MultiView Navigator (MVN).

Figure 8-4 • Snapshot of an I/O Tile

Low power flash device I/Os are implemented using two tile types: I/O and differential I/O (diffio).

The diffio tile is built up using two I/O tiles, which form an I/O pair (P side and N side). These I/O pairs are used according to differential I/O standards. Both the P and N sides of the diffio tile include an I/O buffer and two I/O logic blocks (auxiliary and main logic).

Every minibank (E devices only) is built up from multiple diffio tiles. The number of the minibank depends on the different-size dies. Refer to the "Pro I/Os—IGLOOe, ProASIC3EL, and ProASIC3E" section on page 215 for an illustration of the minibank structure.

Figure 8-5 on page 222 shows a simplified diagram of the I/O buffer circuitry. The Output Enable signal (OE) enables the output buffer to pass the signal from the core logic to the pin. The output buffer contains ESD protection circuitry, an n-channel transistor that shunts all ESD surges (up to the limit of the device ESD specification) to GND. This transistor also serves as an output pull-down resistor.

Each output buffer also contains programmable slew rate, drive strength, programmable power-up state (pull-up/-down resistor), hot-swap, 5 V tolerance, and clamp diode control circuitry. Multiple flash switches (not shown in Figure 8-5 on page 222) are programmed by user selections in the software to activate different I/O features.

Solution 3

The board-level design must ensure that the reflected waveform at the pad does not exceed the voltage overshoot/undershoot limits provided in the datasheet. This is a requirement to ensure long-term reliability.

This scheme will also work for a 3.3 V PCI/PCI-X configuration, but the internal diode should not be used for clamping, and the voltage must be limited by the bus switch, as shown in Figure 8-12. Relying on the diode clamping would create an excessive pad DC voltage of $3.3\text{ V} + 0.7\text{ V} = 4\text{ V}$.

Figure 8-12 • Solution 3

Input Support for DDR

The basic structure to support a DDR input is shown in Figure 10-2. Three input registers are used to capture incoming data, which is presented to the core on each rising edge of the I/O register clock. Each I/O tile supports DDR inputs.

Figure 10-2 • DDR Input Register Support in Low Power Flash Devices

Output Support for DDR

The basic DDR output structure is shown in Figure 10-1 on page 271. New data is presented to the output every half clock cycle.

Note: DDR macros and I/O registers do not require additional routing. The combiner automatically recognizes the DDR macro and pushes its registers to the I/O register area at the edge of the chip. The routing delay from the I/O registers to the I/O buffers is already taken into account in the DDR macro.

Device Programmers

Single Device Programmer

Single device programmers are used to program a device before it is mounted on the system board.

The advantage of using device programmers is that no programming hardware is required on the system board. Therefore, no additional components or board space are required.

Adapter modules are purchased with single device programmers to support the FPGA packages used. The FPGA is placed in the adapter module and the programming software is run from a PC. Microsemi supplies the programming software for all of the Microsemi programmers. The software allows for the selection of the correct die/package and programming files. It will then program and verify the device.

- Single-site programmers

A single-site programmer programs one device at a time. Microsemi offers Silicon Sculptor 3, built by BP Microsystems, as a single-site programmer. Silicon Sculptor 3 and associated software are available only from Microsemi.

- Advantages: Lower cost than multi-site programmers. No additional overhead for programming on the system board. Allows local control of programming and data files for maximum security. Allows on-demand programming on-site.
- Limitations: Only programs one device at a time.

- Multi-site programmers

Often referred to as batch or gang programmers, multi-site programmers can program multiple devices at the same time using the same programming file. This is often used for large volume programming and by programming houses. The sites often have independent processors and memory enabling the sites to operate concurrently, meaning each site may start programming the same file independently. This enables the operator to change one device while the other sites continue programming, which increases throughput. Multiple adapter modules for the same package are required when using a multi-site programmer. Silicon Sculptor I, II, and 3 programmers can be cascaded to program multiple devices in a chain. Multi-site programmers, such as the BP2610 and BP2710, can also be purchased from BP Microsystems. When using BP Microsystems multi-site programmers, users must use programming adapter modules available only from Microsemi. Visit the Microsemi SoC Products Group website to view the part numbers of the desired adapter module:

http://www.microsemi.com/soc/products/hardware/program_debug/ss/modules.aspx.

Also when using BP Microsystems programmers, customers must use Microsemi programming software to ensure the best programming result will occur.

- Advantages: Provides the capability of programming multiple devices at the same time. No additional overhead for programming on the system board. Allows local control of programming and data files for maximum security.
- Limitations: More expensive than a single-site programmer

- Automated production (robotic) programmers

Automated production programmers are based on multi-site programmers. They consist of a large input tray holding multiple parts and a robotic arm to select and place parts into appropriate programming sockets automatically. When the programming of the parts is complete, the parts are removed and placed in a finished tray. The automated programmers are often used in volume programming houses to program parts for which the programming time is small. BP Microsystems part number BP4710, BP4610, BP3710 MK2, and BP3610 are available for this purpose. Auto programmers cannot be used to program RTAX-S devices.

Where an auto-programmer is used, the appropriate open-top adapter module from BP Microsystems must be used.

Figure 12-5 • Example Application Scenario Using AES in Fusion Devices

FlashLock

Additional Options for IGLOO and ProASIC3 Devices

The user also has the option of prohibiting Write operations to the FPGA array but allowing Verify operations on the FPGA array and/or Read operations on the FlashROM without the use of the FlashLock Pass Key. This option provides the user the freedom of verifying the FPGA array and/or reading the FlashROM contents after the device is programmed, without having to provide the FlashLock Pass Key. The user can incorporate AES encryption on the programming files to better enhance the level of security used.

Permanent Security Setting Options

In applications where a permanent lock is not desired, yet the security settings should not be modifiable, IGLOO and ProASIC3 devices can accommodate this requirement.

This application is particularly useful in cases where a device is located at a remote location and must be reprogrammed with a design or data update. Refer to the "Application 3: Nontrusted Environment—Field Updates/Upgrades" section on page 310 for further discussion and examples of how this can be achieved.

The user must be careful when considering the Permanent FlashLock or Permanent Security Settings option. Once the design is programmed with the permanent settings, it is not possible to reconfigure the security settings already employed on the device. Therefore, exercise careful consideration before programming permanent settings.

Permanent FlashLock

The purpose of the permanent lock feature is to provide the benefits of the highest level of security to IGLOO and ProASIC3 devices. If selected, the permanent FlashLock feature will create a permanent barrier, preventing any access to the contents of the device. This is achieved by permanently disabling Write and Verify access to the array, and Write and Read access to the FlashROM. After permanently locking the device, it has been effectively rendered one-time-programmable. This feature is useful if the intended applications do not require design or system updates to the device.

Microprocessor Programming Support in Flash Devices

The flash-based FPGAs listed in Table 15-1 support programming with a microprocessor and the functions described in this document.

Table 15-1 • Flash-Based FPGAs

Series	Family*	Description
IGLOO	IGLOO	Ultra-low power 1.2 V to 1.5 V FPGAs with Flash*Freeze technology
	IGLOOe	Higher density IGLOO FPGAs with six PLLs and additional I/O standards
	IGLOO nano	The industry's lowest-power, smallest-size solution
	IGLOO PLUS	IGLOO FPGAs with enhanced I/O capabilities
ProASIC3	ProASIC3	Low power, high-performance 1.5 V FPGAs
	ProASIC3E	Higher density ProASIC3 FPGAs with six PLLs and additional I/O standards
	ProASIC3 nano	Lowest-cost solution with enhanced I/O capabilities
	ProASIC3L	ProASIC3 FPGAs supporting 1.2 V to 1.5 V with Flash*Freeze technology
	RT ProASIC3	Radiation-tolerant RT3PE600L and RT3PE3000L
	Military ProASIC3/EL	Military temperature A3PE600L, A3P1000, and A3PE3000L
	Automotive ProASIC3	ProASIC3 FPGAs qualified for automotive applications
Fusion	Fusion	Mixed signal FPGA integrating ProASIC3 FPGA fabric, programmable analog block, support for ARM® Cortex™-M1 soft processors, and flash memory into a monolithic device

Note: *The device names link to the appropriate datasheet, including product brief, DC and switching characteristics, and packaging information.

IGLOO Terminology

In documentation, the terms IGLOO series and IGLOO devices refer to all of the IGLOO devices as listed in Table 15-1. Where the information applies to only one device or limited devices, these exclusions will be explicitly stated.

ProASIC3 Terminology

In documentation, the terms ProASIC3 series and ProASIC3 devices refer to all of the ProASIC3 devices as listed in Table 15-1. Where the information applies to only one device or limited devices, these exclusions will be explicitly stated.

To further understand the differences between the IGLOO and ProASIC3 devices, refer to the *Industry's Lowest Power FPGAs Portfolio*.

UJTAG Macro

The UJTAG tiles can be instantiated in a design using the UJTAG macro from the Fusion, IGLOO, or ProASIC3 macro library. Note that "UJTAG" is a reserved name and cannot be used for any other user-defined blocks. A block symbol of the UJTAG tile macro is presented in Figure 17-2. In this figure, the ports on the left side of the block are connected to the JTAG TAP Controller, and the right-side ports are accessible by the FPGA core VersaTiles. The TDI, TMS, TDO, TCK, and TRST ports of UJTAG are only provided for design simulation purposes and should be treated as external signals in the design netlist. However, these ports must NOT be connected to any I/O buffer in the netlist. Figure 17-3 on page 366 illustrates the correct connection of the UJTAG macro to the user design netlist. Microsemi Designer software will automatically connect these ports to the TAP during place-and-route. Table 17-2 gives the port descriptions for the rest of the UJTAG ports:

Table 17-2 • UJTAG Port Descriptions

Port	Description
UIREG [7:0]	This 8-bit bus carries the contents of the JTAG Instruction Register of each device. Instruction Register values 16 to 127 are not reserved and can be employed as user-defined instructions.
URSTB	URSTB is an active-low signal and will be asserted when the TAP Controller is in Test-Logic-Reset mode. URSTB is asserted at power-up, and a power-on reset signal resets the TAP Controller. URSTB will stay asserted until an external TAP access changes the TAP Controller state.
UTDI	This port is directly connected to the TAP's TDI signal.
UTDO	This port is the user TDO output. Inputs to the UTDO port are sent to the TAP TDO output MUX when the IR address is in user range.
UDRSH	Active-high signal enabled in the ShiftDR TAP state
UDRCAP	Active-high signal enabled in the CaptureDR TAP state
UDRCK	This port is directly connected to the TAP's TCK signal.
UDRUPD	Active-high signal enabled in the UpdateDR TAP state

Figure 17-2 • UJTAG Tile Block Symbol

Brownout Voltage

Brownout is a condition in which the voltage supplies are lower than normal, causing the device to malfunction as a result of insufficient power. In general, Microsemi does not guarantee the functionality of the design inside the flash FPGA if voltage supplies are below their minimum recommended operating condition. Microsemi has performed measurements to characterize the brownout levels of FPGA power supplies. Refer to Table 18-3 for device-specific brownout deactivation levels. For the purpose of characterization, a direct path from the device input to output is monitored while voltage supplies are lowered gradually. The brownout point is defined as the voltage level at which the output stops following the input. Characterization tests performed on several IGLOO, ProASIC3L, and ProASIC3 devices in typical operating conditions showed the brownout voltage levels to be within the specification.

During device power-down, the device I/Os become tristated once the first supply in the power-down sequence drops below its brownout deactivation voltage.

Table 18-3 • Brownout Deactivation Levels for VCC and VCCI

Devices	VCC Brownout Deactivation Level (V)	VCCI Brownout Deactivation Level (V)
ProASIC3, ProASIC3 nano, IGLOO, IGLOO nano, IGLOO PLUS and ProASIC3L devices running at VCC = 1.5 V	0.75 V $\pm$ 0.25 V	0.8 V $\pm$ 0.3 V
IGLOO, IGLOO nano, IGLOO PLUS, and ProASIC3L devices running at VCC = 1.2 V	0.75 V $\pm$ 0.2 V	0.8 V $\pm$ 0.15 V

PLL Behavior at Brownout Condition

When PLL power supply voltage and/or V_{CC} levels drop below the V_{CC} brownout levels mentioned above for 1.5 V and 1.2 V devices, the PLL output lock signal goes LOW and/or the output clock is lost. The following sections explain PLL behavior during and after the brownout condition.

VCCPLL and VCC Tied Together

In this condition, both VCC and VCCPLL drop below the 0.75 V ($\pm$ 0.25 V or $\pm$ 0.2 V) brownout level. During the brownout recovery, once VCCPLL and VCC reach the activation point (0.85 $\pm$ 0.25 V or $\pm$ 0.2 V) again, the PLL output lock signal may still remain LOW with the PLL output clock signal toggling. If this condition occurs, there are two ways to recover the PLL output lock signal:

1. Cycle the power supplies of the PLL (power off and on) by using the PLL POWERDOWN signal.
2. Turn off the input reference clock to the PLL and then turn it back on.

Only VCCPLL Is at Brownout

In this case, only VCCPLL drops below the 0.75 V ($\pm$ 0.25 V or $\pm$ 0.2 V) brownout level and the VCC supply remains at nominal recommended operating voltage (1.5 V $\pm$ 0.075 V for 1.5 V devices and 1.2 V $\pm$ 0.06 V for 1.2 V devices). In this condition, the PLL behavior after brownout recovery is similar to initial power-up condition, and the PLL will regain lock automatically after VCCPLL is ramped up above the activation level (0.85 $\pm$ 0.25 V or $\pm$ 0.2 V). No intervention is necessary in this case.

Only VCC Is at Brownout

In this condition, VCC drops below the 0.75 V ($\pm$ 0.25 V or $\pm$ 0.2 V) brownout level and VCCPLL remains at nominal recommended operating voltage (1.5 V $\pm$ 0.075 V for 1.5 V devices and 1.2 V $\pm$ 0.06 V for 1.2 V devices). During the brownout recovery, once VCC reaches the activation point again (0.85 $\pm$ 0.25 V or $\pm$ 0.2 V), the PLL output lock signal may still remain LOW with the PLL output clock signal toggling. If this condition occurs, there are two ways to recover the PLL output lock signal:

1. Cycle the power supplies of the PLL (power off and on) by using the PLL POWERDOWN signal.
2. Turn off the input reference clock to the PLL and then turn it back on.

It is important to note that Microsemi recommends using a monotonic power supply or voltage regulator to ensure proper power-up behavior.
