Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Obsolete
Number of LABs/CLBs	-
Number of Logic Elements/Cells	-
Total RAM Bits	36864
Number of I/O	68
Number of Gates	250000
Voltage - Supply	1.14V ~ 1.575V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 85°C (TJ)
Package / Case	100-TQFP
Supplier Device Package	100-VQFP (14x14)
Purchase URL	https://www.e-xfl.com/product-detail/microsemi/a3p250l-vq100

Flash*Freeze Mode

IGLOO, IGLOO nano, IGLOO PLUS, ProASIC3L, and RT ProASIC3 FPGAs offer an ultra-low static power mode to reduce power consumption while preserving the state of the registers, SRAM contents, and I/O states (IGLOO nano and IGLOO PLUS only) without switching off any power supplies, inputs, or input clocks.

Flash*Freeze technology enables the user to switch to Flash*Freeze mode within 1 μ s, thus simplifying low power design implementation. The Flash*Freeze (FF) pin (active Low) is a dedicated pin used to enter or exit Flash*Freeze mode directly; or the pin can be routed internally to the FPGA core and state management IP to allow the user's application to decide if and when it is safe to transition to this mode. If the FF pin is not used, it can be used as a regular I/O.

The FF pin has a built-in glitch filter and optional Schmitt trigger (not available for all devices) to prevent entering or exiting Flash*Freeze mode accidentally.

There are two ways to use Flash*Freeze mode. In Flash*Freeze type 1, entering and exiting the mode is exclusively controlled by the assertion and deassertion of the FF pin. This enables an external processor or human interface device to directly control Flash*Freeze mode; however, valid data must be preserved using standard procedures (refer to the "Flash*Freeze Mode Device Behavior" section on page 30). In Flash*Freeze mode type 2, entering and exiting the mode is controlled by both the FF pin AND user-defined logic. Flash*Freeze management IP may be used in type 2 mode for clock and data management while entering and exiting Flash*Freeze mode.

Flash*Freeze Type 1: Control by Dedicated Flash*Freeze Pin

Flash*Freeze type 1 is intended for systems where either the device will be reset upon exiting Flash*Freeze mode, or data and clock are managed externally. The device enters Flash*Freeze mode 1 μ s after the dedicated FF pin is asserted (active Low), and returns to normal operation when the FF pin is deasserted (High) (Figure 2-1 on page 25). In this mode, FF pin assertion or deassertion is the only condition that determines entering or exiting Flash*Freeze mode.

In Libero[®] System-on-Chip (SoC) software v8.2 and before, this mode is implemented by enabling Flash*Freeze mode (default setting) in the Compile options of the Microsemi Designer software. To simplify usage of Flash*Freeze mode, beginning with Libero software v8.3, an INBUF_FF I/O macro was introduced. An INBUF_FF I/O buffer must be used to identify the Flash*Freeze input. Microsemi recommends switching to the new implementation.

In Libero software v8.3 and later, the user must manually instantiate the INBUF_FF macro in the top level of the design to implement Flash*Freeze Type 1, as shown in Figure 2-1 on page 25.

Date	Changes	Page
v2.1 (October 2008)	The title changed from "Flash*Freeze Technology and Low Power Modes in IGLOO, IGLOO PLUS, and ProASIC3L Devices" to Actel's Flash*Freeze Technology and Low Power Modes."	N/A
	The "Flash Families Support the Flash*Freeze Feature" section was updated.	22
	Significant changes were made to this document to support Libero IDE v8.4 and later functionality. RT ProASIC3 device support information is new. In addition to the other major changes, the following tables and figures were updated or are new: Figure 2-3 • Flash*Freeze Mode Type 2 – Controlled by Flash*Freeze Pin and Internal Logic (LSICC signal) – updated	27
	Figure 2-5 • Narrow Clock Pulses During Flash*Freeze Entrance and Exit – new	30
	Figure 2-10 • Flash*Freeze Management IP Block Diagram – new Figure 2-11 • FSM State Diagram – new Table 2-6 • IGLOO nano and IGLOO PLUS Flash*Freeze Mode (type 1 and type 2)—I/O Pad State – updated Please review the entire document carefully.	37 38 29
v1.3 (June 2008)	The family description for ProASIC3L in Table 2-1 • Flash-Based FPGAs was updated to include 1.5 V.	22
v1.2 (March 2008)	The part number for this document was changed from 51700094-003-1 to 51700094-004-2.	N/A
	The title of the document was changed to "Flash*Freeze Technology and Low Power Modes in IGLOO, IGLOO PLUS, and ProASIC3L Devices."	N/A
	The "Flash*Freeze Technology and Low Power Modes" section was updated to remove the parenthetical phrase, "from 25 μ W," in the second paragraph. The following sentence was added to the third paragraph: "IGLOO PLUS has an additional feature when operating in Flash*Freeze mode, allowing it to retain I/O states as well as SRAM and register states."	21
	The "Power Conservation Techniques" section was updated to add V _{JTAG} to the parenthetical list of power supplies that should be tied to the ground plane if unused. Additional information was added regarding how the software configures unused I/Os.	2-1
	Table 2-1 • Flash-Based FPGAs and the accompanying text was updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "ProASIC3 Terminology" section are new.	22
	The "Flash*Freeze Mode" section was revised to include that I/O states are preserved in Flash*Freeze mode for IGLOO PLUS devices. The last sentence in the second paragraph was changed to, "If the FF pin is not used, it can be used as a regular I/O." The following sentence was added for Flash*Freeze mode type 2: "Exiting the mode is controlled by either the FF pin OR the user-defined LSICC signal."	24
	The "Flash*Freeze Type 1: Control by Dedicated Flash*Freeze Pin" section was revised to change instructions for implementing this mode, including instructions for implementation with Libero IDE v8.3.	24
	Figure 2-1 • Flash*Freeze Mode Type 1 – Controlled by the Flash*Freeze Pin was updated.	25
	The "Flash*Freeze Type 2: Control by Dedicated Flash*Freeze Pin and Internal Logic" section was renamed from "Type 2 Software Implementation."	26
	The "Type 2 Software Implementation for Libero IDE v8.3" section is new.	2-6

VersaNet Global Network Distribution

One of the architectural benefits of low power flash architecture is the set of powerful, low-delay VersaNet global networks that can access the VersaTiles, SRAM, and I/O tiles of the device. Each device offers a chip global network with six global lines (except for nano 10 k, 15 k, and 20 k gate devices) that are distributed from the center of the FPGA array. In addition, each device (except the 10 k through 30 k gate device) has four quadrant global networks, each consisting of three quadrant global net resources. These quadrant global networks can only drive a signal inside their own quadrant. Each VersaTile has access to nine global line resources—three quadrant and six chip-wide (main) global networks—and a total of 18 globals are available on the device (3×4 regional from each quadrant and 6 global).

Figure 3-1 shows an overview of the VersaNet global network and device architecture for devices 60 k and above. Figure 3-2 and Figure 3-3 on page 50 show simplified VersaNet global networks.

The VersaNet global networks are segmented and consist of spines, global ribs, and global multiplexers (MUXes), as shown in Figure 3-1. The global networks are driven from the global rib at the center of the die or quadrant global networks at the north or south side of the die. The global network uses the MUX trees to access the spine, and the spine uses the clock ribs to access the VersaTile. Access is available to the chip or quadrant global networks and the spines through the global MUXes. Access to the spine using the global MUXes is explained in the "Spine Architecture" section on page 57.

These VersaNet global networks offer fast, low-skew routing resources for high-fanout nets, including clock signals. In addition, these highly segmented global networks offer users the flexibility to create low-skew local clock networks using spines for up to 252 internal/external clocks or other high-fanout nets in low power flash devices. Optimal usage of these low-skew networks can result in significant improvement in design performance.

Note: Not applicable to 10 k through 30 k gate devices

Figure 3-1 • Overview of VersaNet Global Network and Device Architecture

standard for CLKBUF is LVTTTL in the current Microsemi Libero® System-on-Chip (SoC) and Designer software.

Table 3-9 • I/O Standards within CLKBUF

Name	Description
CLKBUF_LVCMOS5	LVCMOS clock buffer with 5.0 V CMOS voltage level
CLKBUF_LVCMOS33	LVCMOS clock buffer with 3.3 V CMOS voltage level
CLKBUF_LVCMOS25	LVCMOS clock buffer with 2.5 V CMOS voltage level ¹
CLKBUF_LVCMOS18	LVCMOS clock buffer with 1.8 V CMOS voltage level
CLKBUF_LVCMOS15	LVCMOS clock buffer with 1.5 V CMOS voltage level
CLKBUF_LVCMOS12	LVCMOS clock buffer with 1.2 V CMOS voltage level
CLKBUF_PCI	PCI clock buffer
CLKBUF_PCIX	PCIX clock buffer
CLKBUF_GTL25	GTL clock buffer with 2.5 V CMOS voltage level ¹
CLKBUF_GTL33	GTL clock buffer with 3.3 V CMOS voltage level ¹
CLKBUF_GTLP25	GTL+ clock buffer with 2.5 V CMOS voltage level ¹
CLKBUF_GTLP33	GTL+ clock buffer with 3.3 V CMOS voltage level ¹
CLKBUF_HSTL_I	HSTL Class I clock buffer ¹
CLKBUF_HSTL_II	HSTL Class II clock buffer ¹
CLKBUF_SSTL2_I	SSTL2 Class I clock buffer ¹
CLKBUF_SSTL2_II	SSTL2 Class II clock buffer ¹
CLKBUF_SSTL3_I	SSTL3 Class I clock buffer ¹
CLKBUF_SSTL3_II	SSTL3 Class II clock buffer ¹

Notes:

1. Supported in only the IGLOOe, ProASIC3E, AFS600, and AFS1500 devices
2. By default, the CLKBUF macro uses the 3.3 V LVTTTL I/O technology.

The current synthesis tool libraries only infer the CLKBUF or CLKINT macros in the netlist. All other global macros must be instantiated manually into your HDL code. The following is an example of CLKBUF_LVCMOS25 global macro instantiations that you can copy and paste into your code:

VHDL

```
component clkbuf_lvcmos25
  port (pad : in std_logic; y : out std_logic);
end component

begin
  -- concurrent statements
  u2 : clkbuf_lvcmos25 port map (pad => ext_clk, y => int_clk);
end
```

Verilog

```
module design (____);

  input ____;
  output ____;

  clkbuf_lvcmos25 u2 (.y(int_clk), .pad(ext_clk));

endmodule
```

4 – Clock Conditioning Circuits in Low Power Flash Devices and Mixed Signal FPGAs

Introduction

This document outlines the following device information: Clock Conditioning Circuit (CCC) features, PLL core specifications, functional descriptions, software configuration information, detailed usage information, recommended board-level considerations, and other considerations concerning clock conditioning circuits and global networks in low power flash devices or mixed signal FPGAs.

Overview of Clock Conditioning Circuitry

In Fusion, IGLOO, and ProASIC3 devices, the CCCs are used to implement frequency division, frequency multiplication, phase shifting, and delay operations. The CCCs are available in six chip locations—each of the four chip corners and the middle of the east and west chip sides. For device-specific variations, refer to the "Device-Specific Layout" section on page 94.

The CCC is composed of the following:

- PLL core
- 3 phase selectors
- 6 programmable delays and 1 fixed delay that advances/delays phase
- 5 programmable frequency dividers that provide frequency multiplication/division (not shown in Figure 4-6 on page 87 because they are automatically configured based on the user's required frequencies)
- 1 dynamic shift register that provides CCC dynamic reconfiguration capability

Figure 4-1 provides a simplified block diagram of the physical implementation of the building blocks in each of the CCCs.

Figure 4-1 • Overview of the CCCs Offered in Fusion, IGLOO, and ProASIC3

Each CCC can implement up to three independent global buffers (with or without programmable delay) or a PLL function (programmable frequency division/multiplication, phase shift, and delays) with up to three global outputs. Unused global outputs of a PLL can be used to implement independent global buffers, up to a maximum of three global outputs for a given CCC.

CCC Programming

The CCC block is fully configurable, either via flash configuration bits set in the programming bitstream or through an asynchronous interface. This asynchronous dedicated shift register interface is dynamically accessible from inside the low power flash devices to permit parameter changes, such as PLL divide ratios and delays, during device operation.

To increase the versatility and flexibility of the clock conditioning system, the CCC configuration is determined either by the user during the design process, with configuration data being stored in flash memory as part of the device programming procedure, or by writing data into a dedicated shift register during normal device operation.

This latter mode allows the user to dynamically reconfigure the CCC without the need for core programming. The shift register is accessed through a simple serial interface. Refer to the "UJTAG Applications in Microsemi's Low Power Flash Devices" section on page 363 or the application note *Using Global Resources in Actel Fusion Devices*.

Global Resources

Low power flash and mixed signal devices provide three global routing networks (GLA, GLB, and GLC) for each of the CCC locations. There are potentially many I/O locations; each global I/O location can be chosen from only one of three possibilities. This is controlled by the multiplexer tree circuitry in each global network. Once the I/O location is selected, the user has the option to utilize the CCCs before the signals are connected to the global networks. The CCC in each location (up to six) has the same structure, so generating the CCC macros is always done with an identical software GUI. The CCCs in the corner locations drive the quadrant global networks, and the CCCs in the middle of the east and west chip sides drive the chip global networks. The quadrant global networks span only a quarter of the device, while the chip global networks span the entire device. For more details on global resources offered in low power flash devices, refer to the "Global Resources in Low Power Flash Devices" section on page 47.

A global buffer can be placed in any of the three global locations (CLKA-GLA, CLKB-GLB, or CLKC-GLC) of a given CCC. A PLL macro uses the CLKA CCC input to drive its reference clock. It uses the GLA and, optionally, the GLB and GLC global outputs to drive the global networks. A PLL macro can also drive the YB and YC regular core outputs. The GLB (or GLC) global output cannot be reused if the YB (or YC) output is used. Refer to the "PLL Macro Signal Descriptions" section on page 84 for more information.

Each global buffer, as well as the PLL reference clock, can be driven from one of the following:

- 3 dedicated single-ended I/Os using a hardwired connection
- 2 dedicated differential I/Os using a hardwired connection (not supported for IGLOO nano or ProASIC3 nano devices)
- The FPGA core

PLL Macro Signal Descriptions

The PLL macro supports two inputs and up to six outputs. Table 4-3 gives a description of each signal.

Table 4-3 • Input and Output Signals of the PLL Block

Signal	Name	I/O	Description
CLKA	Reference Clock	Input	Reference clock input for PLL core; input clock for primary output clock, GLA
OADIVRST	Reset Signal for the Output Divider A	Input	For Fusion only. OADIVRST can be used when you bypass the PLL core (i.e., OAMUX = 001). The purpose of the OADIVRST signals is to reset the output of the final clock divider to synchronize it with the input to that divider when the PLL is bypassed. The signal is active on a low to high transition. The signal must be low for at least one divider input. If PLL core is used, this signal is "don't care" and the internal circuitry will generate the reset signal for the synchronization purpose.
OADIVHALF	Output A Division by Half	Input	For Fusion only. Active high. Division by half feature. This feature can only be used when users bypass the PLL core (i.e., OAMUX = 001) and the RC Oscillator (RCOSC) drives the CLKA input. This can be used to divide the 100 MHz RC oscillator by a factor of 1.5, 2.5, 3.5, 4.5 ... 14.5). Refer to Table 4-18 on page 111 for more information.
EXTFB	External Feedback	Input	Allows an external signal to be compared to a reference clock in the PLL core's phase detector.
POWERDOWN	Power Down	Input	Active low input that selects power-down mode and disables the PLL. With the POWERDOWN signal asserted, the PLL core sends 0 V signals on all of the outputs.
GLA	Primary Output	Output	Primary output clock to respective global/quadrant clock networks
GLB	Secondary 1 Output	Output	Secondary 1 output clock to respective global/quadrant clock networks
YB	Core 1 Output	Output	Core 1 output clock to local routing network
GLC	Secondary 2 Output	Output	Secondary 2 output clock to respective global/quadrant clock networks
YC	Core 2 Output	Output	Core 2 output clock to local routing network
LOCK	PLL Lock Indicator	Output	Active high signal indicating that steady-state lock has been achieved between CLKA and the PLL feedback signal

Input Clock

The inputs to the input reference clock (CLKA) of the PLL can come from global input pins, regular I/O pins, or internally from the core. For Fusion families, the input reference clock can also be from the embedded RC oscillator or crystal oscillator.

Global Output Clocks

GLA (Primary), GLB (Secondary 1), and GLC (Secondary 2) are the outputs of Global Multiplexer 1, Global Multiplexer 2, and Global Multiplexer 3, respectively. These signals (GLx) can be used to drive the high-speed global and quadrant networks of the low power flash devices.

A global multiplexer block consists of the input routing for selecting the input signal for the GLx clock and the output multiplexer, as well as delay elements associated with that clock.

Core Output Clocks

YB and YC are known as Core Outputs and can be used to drive internal logic without using global network resources. This is especially helpful when global network resources must be conserved and utilized for other timing-critical paths.

Figure 6-2 • Fusion Device Architecture Overview (AFS600)

The ROM emulation application is based on RAM block initialization. If the user's main design has access only to the read ports of the RAM block (RADDR, RD, RCLK, and REN), and the contents of the RAM are already initialized through the TAP, then the memory blocks will emulate ROM functionality for the core design. In this case, the write ports of the RAM blocks are accessed only by the user interface block, and the interface is activated only by the TAP Instruction Register contents.

Users should note that the contents of the RAM blocks are lost in the absence of applied power. However, the 1 kbit of flash memory, FlashROM, in low power flash devices can be used to retain data after power is removed from the device. Refer to the "SRAM and FIFO Memories in Microsemi's Low Power Flash Devices" section on page 147 for more information.

Sample Verilog Code

Interface Block

```
`define Initialize_start 8'h22 //INITIALIZATION START COMMAND VALUE
`define Initialize_stop 8'h23 //INITIALIZATION START COMMAND VALUE

module interface(IR, rst_n, data_shift, clk_in, data_update, din_ser, dout_ser, test,

Date	Changes	Page
v1.1 (continued)	Table 6-1 • Flash-Based FPGAs and associated text were updated to include the IGLOO PLUS family. The "IGLOO Terminology" section and "ProASIC3 Terminology" section are new.	150
	The text introducing Table 6-8 • Memory Availability per IGLOO and ProASIC3 Device was updated to replace "A3P030 and AGL030" with "15 k and 30 k gate devices." Table 6-8 • Memory Availability per IGLOO and ProASIC3 Device was updated to remove AGL400 and AGL1500 and include IGLOO PLUS and ProASIC3L devices.	162

IGLOO and ProASIC3

For boards and cards with three levels of staging, card power supplies must have time to reach their final values before the I/Os are connected. Pay attention to the sizing of power supply decoupling capacitors on the card to ensure that the power supplies are not overloaded with capacitance.

Cards with three levels of staging should have the following sequence:

- Grounds
- Powers
- I/Os and other pins

For Level 3 and Level 4 compliance with the 30K gate device, cards with two levels of staging should have the following sequence:

- Grounds
- Powers, I/Os, and other pins

Cold-Sparing Support

Cold-sparing refers to the ability of a device to leave system data undisturbed when the system is powered up, while the component itself is powered down, or when power supplies are floating.

The resistor value is calculated based on the decoupling capacitance on a given power supply. The RC constant should be greater than 3 μ s.

To remove resistor current during operation, it is suggested that the resistor be disconnected (e.g., with an NMOS switch) from the power supply after the supply has reached its final value. Refer to the "Power-Up/Down Behavior of Low Power Flash Devices" section on page 373 for details on cold-sparing.

Cold-sparing means that a subsystem with no power applied (usually a circuit board) is electrically connected to the system that is in operation. This means that all input buffers of the subsystem must present very high input impedance with no power applied so as not to disturb the operating portion of the system.

The 30 k gate devices fully support cold-sparing, since the I/O clamp diode is always off (see Table 7-12 on page 193). If the 30 k gate device is used in applications requiring cold-sparing, a discharge path from the power supply to ground should be provided. This can be done with a discharge resistor or a switched resistor. This is necessary because the 30K gate devices do not have built-in I/O clamp diodes.

For other IGLOO and ProASIC3 devices, since the I/O clamp diode is always active, cold-sparing can be accomplished either by employing a bus switch to isolate the device I/Os from the rest of the system or by driving each I/O pin to 0 V. If the resistor is chosen, the resistor value must be calculated based on decoupling capacitance on a given power supply on the board (this decoupling capacitance is in parallel with the resistor). The RC time constant should ensure full discharge of supplies before cold-sparing functionality is required. The resistor is necessary to ensure that the power pins are discharged to ground every time there is an interruption of power to the device.

IGLOOe and ProASIC3E devices support cold-sparing for all I/O configurations. Standards, such as PCI, that require I/O clamp diodes can also achieve cold-sparing compliance, since clamp diodes get disconnected internally when the supplies are at 0 V.

When targeting low power applications, I/O cold-sparing may add additional current if a pin is configured with either a pull-up or pull-down resistor and driven in the opposite direction. A small static current is induced on each I/O pin when the pin is driven to a voltage opposite to the weak pull resistor. The current is equal to the voltage drop across the input pin divided by the pull resistor. Refer to the "Detailed I/O DC Characteristics" section of the appropriate family datasheet for the specific pull resistor value for the corresponding I/O standard.

For example, assuming an LVTTTL 3.3 V input pin is configured with a weak pull-up resistor, a current will flow through the pull-up resistor if the input pin is driven LOW. For LVTTTL 3.3 V, the pull-up resistor is ~45 k Ω , and the resulting current is equal to $3.3 \text{ V} / 45 \text{ k}\Omega = 73 \text{ }\mu\text{A}$ for the I/O pin. This is true also when a weak pull-down is chosen and the input pin is driven HIGH. This current can be avoided by driving the input LOW when a weak pull-down resistor is used and driving it HIGH when a weak pull-up resistor is used.

This current draw can occur in the following cases:

Low power flash devices feature a flexible I/O structure, supporting a range of mixed voltages (1.2 V, 1.5 V, 1.8 V, 2.5 V, and 3.3 V) through bank-selectable voltages. IGLOO[®]e, ProASIC[®]3EL, and ProASIC3E families support Pro I/Os.

Users designing I/O solutions are faced with a number of implementation decisions and configuration choices that can directly impact the efficiency and effectiveness of their final design. The flexible I/O structure, supporting a wide variety of voltages and I/O standards, enables users to meet the growing challenges of their many diverse applications. The Libero SoC software provides an easy way to implement I/O that will result in robust I/O design.

This document first describes the two different I/O types in terms of the standards and features they support. It then explains the individual features and how to implement them in Libero SoC.

Figure 8-1 • DDR Configured I/O Block Logical Representation

I/O Standards

Single-Ended Standards

These I/O standards use a push-pull CMOS output stage with a voltage referenced to system ground to designate logical states. The input buffer configuration, output drive, and I/O supply voltage (V_{CCI}) vary among the I/O standards (Figure 8-6).

Figure 8-6 • Single-Ended I/O Standard Topology

The advantage of these standards is that a common ground can be used for multiple I/Os. This simplifies board layout and reduces system cost. Their low-edge-rate (dv/dt) data transmission causes less electromagnetic interference (EMI) on the board. However, they are not suitable for high-frequency (>200 MHz) switching due to noise impact and higher power consumption.

LVTTL (Low-Voltage TTL)

This is a general-purpose standard (EIA/JESD8-B) for 3.3 V applications. It uses an LVTTL input buffer and a push-pull output buffer. The LVTTL output buffer can have up to six different programmable drive strengths. The default drive strength is 12 mA. V_{CCI} is 3.3 V. Refer to "I/O Programmable Features" on page 227 for details.

LVC MOS (Low-Voltage CMOS)

The low power flash devices provide four different kinds of LVC MOS: LVC MOS 3.3 V, LVC MOS 2.5 V, LVC MOS 1.8 V, and LVC MOS 1.5 V. LVC MOS 3.3 V is an extension of the LVC MOS standard (JESD8-B-compliant) used for general-purpose 3.3 V applications. LVC MOS 2.5 V is an extension of the LVC MOS standard (JESD8-5-compliant) used for general-purpose 2.5 V applications. LVC MOS 2.5 V for the 30 k gate devices has a clamp diode to V_{CCI} , but for all other devices there is no clamp diode.

There is yet another standard supported by IGLOO and ProASIC3 devices (except A3P030): LVC MOS 2.5/5.0 V. This standard is similar to LVC MOS 2.5 V, with the exception that it can support up to 3.3 V on the input side (2.5 V output drive).

LVC MOS 1.8 V is an extension of the LVC MOS standard (JESD8-7-compliant) used for general-purpose 1.8 V applications. LVC MOS 1.5 V is an extension of the LVC MOS standard (JESD8-11-compliant) used for general-purpose 1.5 V applications.

The V_{CCI} values for these standards are 3.3 V, 2.5 V, 1.8 V, and 1.5 V, respectively. Like LVTTL, the output buffer has up to seven different programmable drive strengths (2, 4, 6, 8, 12, 16, and 24 mA). Refer to "I/O Programmable Features" on page 227 for details.

3.3 V PCI (Peripheral Component Interface)

This standard specifies support for both 33 MHz and 66 MHz PCI bus applications. It uses an LVTTL input buffer and a push-pull output buffer. With the aid of an external resistor, this I/O standard can be 5 V-compliant for low power flash devices. It does not have programmable drive strength.

3.3 V PCI-X (Peripheral Component Interface Extended)

An enhanced version of the PCI specification, 3.3 V PCI-X can support higher average bandwidths; it increases the speed that data can move within a computer from 66 MHz to 133 MHz. It is backward-

IGLOOe and ProASIC3E

For devices requiring Level 3 and/or Level 4 compliance, the board drivers connected to the I/Os must have 10 k Ω (or lower) output drive resistance at hot insertion, and 1 k Ω (or lower) output drive resistance at hot removal. This resistance is the transmitter resistance sending a signal toward the I/O, and no additional resistance is needed on the board. If that cannot be assured, three levels of staging can be used to achieve Level 3 and/or Level 4 compliance. Cards with two levels of staging should have the following sequence:

- Grounds
- Powers, I/Os, and other pins

Cold-Sparing Support

Cold-sparing refers to the ability of a device to leave system data undisturbed when the system is powered up, while the component itself is powered down, or when power supplies are floating.

Cold-sparing is supported on ProASIC3E devices only when the user provides resistors from each power supply to ground. The resistor value is calculated based on the decoupling capacitance on a given power supply. The RC constant should be greater than 3 μ s.

To remove resistor current during operation, it is suggested that the resistor be disconnected (e.g., with an NMOS switch) from the power supply after the supply has reached its final value. Refer to the "Power-Up/Down Behavior of Low Power Flash Devices" section on page 373 for details on cold-sparing.

Cold-sparing means that a subsystem with no power applied (usually a circuit board) is electrically connected to the system that is in operation. This means that all input buffers of the subsystem must present very high input impedance with no power applied so as not to disturb the operating portion of the system.

The 30 k gate devices fully support cold-sparing, since the I/O clamp diode is always off (see Table 8-13 on page 231). If the 30 k gate device is used in applications requiring cold-sparing, a discharge path from the power supply to ground should be provided. This can be done with a discharge resistor or a switched resistor. This is necessary because the 30 k gate devices do not have built-in I/O clamp diodes.

For other IGLOOe and ProASIC3E devices, since the I/O clamp diode is always active, cold-sparing can be accomplished either by employing a bus switch to isolate the device I/Os from the rest of the system or by driving each I/O pin to 0 V. If the resistor is chosen, the resistor value must be calculated based on decoupling capacitance on a given power supply on the board (this decoupling capacitance is in parallel with the resistor). The RC time constant should ensure full discharge of supplies before cold-sparing functionality is required. The resistor is necessary to ensure that the power pins are discharged to ground every time there is an interruption of power to the device.

IGLOOe and ProASIC3E devices support cold-sparing for all I/O configurations. Standards, such as PCI, that require I/O clamp diodes can also achieve cold-sparing compliance, since clamp diodes get disconnected internally when the supplies are at 0 V.

When targeting low power applications, I/O cold-sparing may add additional current if a pin is configured with either a pull-up or pull-down resistor and driven in the opposite direction. A small static current is induced on each I/O pin when the pin is driven to a voltage opposite to the weak pull resistor. The current is equal to the voltage drop across the input pin divided by the pull resistor. Refer to the "Detailed I/O DC Characteristics" section of the appropriate family datasheet for the specific pull resistor value for the corresponding I/O standard.

For example, assuming an LVTTTL 3.3 V input pin is configured with a weak pull-up resistor, a current will flow through the pull-up resistor if the input pin is driven LOW. For LVTTTL 3.3 V, the pull-up resistor is ~45 k Ω , and the resulting current is equal to $3.3 \text{ V} / 45 \text{ k}\Omega = 73 \mu\text{A}$ for the I/O pin. This is true also when a weak pull-down is chosen and the input pin is driven High. This current can be avoided by driving the input Low when a weak pull-down resistor is used and driving it High when a weak pull-up resistor is used.

This current draw can occur in the following cases:

- In Active and Static modes:
 - Input buffers with pull-up, driven Low
 - Input buffers with pull-down, driven High
 - Bidirectional buffers with pull-up, driven Low
 - Bidirectional buffers with pull-down, driven High
 - Output buffers with pull-up, driven Low
 - Output buffers with pull-down, driven High
 - Tristate buffers with pull-up, driven Low
 - Tristate buffers with pull-down, driven High
- In Flash*Freeze mode:
 - Input buffers with pull-up, driven Low
 - Input buffers with pull-down, driven High
 - Bidirectional buffers with pull-up, driven Low
 - Bidirectional buffers with pull-down, driven High

Electrostatic Discharge Protection

Low power flash devices are tested per JEDEC Standard JESD22-A114-B.

These devices contain clamp diodes at every I/O, global, and power pad. Clamp diodes protect all device pads against damage from ESD as well as from excessive voltage transients.

All IGLOO and ProASIC3 devices are tested to the Human Body Model (HBM) and the Charged Device Model (CDM).

Each I/O has two clamp diodes. One diode has its positive (P) side connected to the pad and its negative (N) side connected to VCCI. The second diode has its P side connected to GND and its N side connected to the pad. During operation, these diodes are normally biased in the off state, except when transient voltage is significantly above VCCI or below GND levels.

In 30 k gate devices, the first diode is always off. In other devices, the clamp diode is always on and cannot be switched off.

By selecting the appropriate I/O configuration, the diode is turned on or off. Refer to Table 8-13 for more information about the I/O standards and the clamp diode.

The second diode is always connected to the pad, regardless of the I/O configuration selected.

Table 8-13 • I/O Hot-Swap and 5 V Input Tolerance Capabilities in IGLOOe and ProASIC3E Devices

I/O Assignment	Clamp Diode	Hot Insertion	5 V Input Tolerance	Input Buffer	Output Buffer
3.3 V LVTTTL/LVCMOS	No	Yes	Yes ¹	Enabled/Disabled	
3.3 V PCI, 3.3 V PCI-X	Yes	No	Yes ¹	Enabled/Disabled	
LVCMOS 2.5 V ²	No	Yes	No	Enabled/Disabled	
LVCMOS 2.5 V / 5.0 V ²	Yes	No	Yes ³	Enabled/Disabled	
LVCMOS 1.8 V	No	Yes	No	Enabled/Disabled	
LVCMOS 1.5 V	No	Yes	No	Enabled/Disabled	
Voltage-Referenced Input Buffer	No	Yes	No	Enabled/Disabled	
Differential, LVDS/B-LVDS/M-LVDS/LVPECL	No	Yes	No	Enabled/Disabled	

Notes:

1. Can be implemented with an external IDT bus switch, resistor divider, or Zener with resistor.
2. In the SmartGen Core Reference Guide, select the LVCMOS5 macro for the LVCMOS 2.5 V / 5.0 V I/O standard or the LVCMOS25 macro for the LVCMOS 2.5 V I/O standard.
3. Can be implemented with an external resistor and an internal clamp diode.

User I/O Naming Convention

IGLOOe and ProASIC3E

Due to the comprehensive and flexible nature of IGLOOe and ProASIC3E device user I/Os, a naming scheme is used to show the details of each I/O (Figure 8-20 on page 246). The name identifies to which I/O bank it belongs, as well as the pairing and pin polarity for differential I/Os.

I/O Nomenclature = FF/Gmn/IOuxwByVz

Gmn is only used for I/Os that also have CCC access—i.e., global pins.

FF = Indicates the I/O dedicated for the Flash*Freeze mode activation pin in IGLOOe only

G = Global

m = Global pin location associated with each CCC on the device: A (northwest corner), B (northeast corner), C (east middle), D (southeast corner), E (southwest corner), and F (west middle)

n = Global input MUX and pin number of the associated Global location m, either A0, A1, A2, B0, B1, B2, C0, C1, or C2. Refer to the "Global Resources in Low Power Flash Devices" section on page 47 for information about the three input pins per clock source MUX at CCC location m.

u = I/O pair number in the bank, starting at 00 from the northwest I/O bank and proceeding in a clockwise direction

x = P (Positive) or N (Negative) for differential pairs, or R (Regular—single-ended) for the I/Os that support single-ended and voltage-referenced I/O standards only

w = D (Differential Pair), P (Pair), or S (Single-Ended). D (Differential Pair) if both members of the pair are bonded out to adjacent pins or are separated only by one GND or NC pin; P (Pair) if both members of the pair are bonded out but do not meet the adjacency requirement; or S (Single-Ended) if the I/O pair is not bonded out. For Differential (D) pairs, adjacency for ball grid packages means only vertical or horizontal. Diagonal adjacency does not meet the requirements for a true differential pair.

B = Bank

y = Bank number (0–7). The bank number starts at 0 from the northwest I/O bank and proceeds in a clockwise direction.

V = V_{REF}

z = V_{REF} minibank number (0–4). A given voltage-referenced signal spans 16 pins (typically) in an I/O bank. Voltage banks may have multiple V_{REF} minibanks.

Automatically Assigning Technologies to I/O Banks

The I/O Bank Assigner (IOBA) tool runs automatically when you run Layout. You can also use this tool from within the MultiView Navigator (Figure 9-17). The IOBA tool automatically assigns technologies and VREF pins (if required) to every I/O bank that does not currently have any technologies assigned to it. This tool is available when at least one I/O bank is unassigned.

To automatically assign technologies to I/O banks, choose I/O Bank Assigner from the **Tools** menu (or click the I/O Bank Assigner's toolbar button, shown in Figure 9-16).

Figure 9-16 • I/O Bank Assigner's Toolbar Button

Messages will appear in the Output window informing you when the automatic I/O bank assignment begins and ends. If the assignment is successful, the message "I/O Bank Assigner completed successfully" appears in the Output window, as shown in Figure 9-17.
